**Addendum November 2016**

This report is based on research conducted by the Pacific Northwest Evidence-based Practice Center (EPC) under contract to the Agency for Healthcare Research and Quality (AHRQ), Rockville, MD (Contract No. 290-2012-00014-I). The findings and conclusions in this document are those of the authors, who are responsible for its contents; the findings and conclusions do not necessarily represent the views of AHRQ. Therefore, no statement in this report should be construed as an official position of AHRQ or of the U.S. Department of Health and Human Services.

The information in this report is intended to help health care decisionmakers—patients and clinicians, health system leaders, and policymakers, among others—make well-informed decisions and thereby improve the quality of health care services. This report is not intended to be a substitute for the application of clinical judgment. Anyone who makes decisions concerning the provision of clinical care should consider this report in the same way as any medical reference and in conjunction with all other pertinent information, i.e., in the context of available resources and circumstances presented by individual patients.

AHRQ or U.S. Department of Health and Human Services endorsement of any derivative products that may be developed from this report, such as clinical practice guidelines, other quality enhancement tools, or reimbursement or coverage policies, may not be stated or implied.

This report may periodically be assessed for the currency of conclusions. If an assessment is done, the resulting surveillance report describing the methodology and findings will be found on the Effective Health Care Program Web site at [www.effectivehealthcare.ahrq.gov](http://www.effectivehealthcare.ahrq.gov). Search on the title of the report.

This document is in the public domain and may be used and reprinted without permission. Citation of the source is appreciated.

Persons using assistive technology may not be able to fully access information in this report. For assistance contact [EffectiveHealthCare@ahrq.hhs.gov](mailto:EffectiveHealthCare@ahrq.hhs.gov).

None of the investigators have any affiliations or financial involvement that conflicts with the material presented in this report.

## Preface

The Agency for Healthcare Research and Quality (AHRQ), through its Evidence-based Practice Centers (EPCs), sponsors the development of systematic reviews to assist public- and private-sector organizations in their efforts to improve the quality of health care in the United States. These reviews provide comprehensive, science-based information on common, costly medical conditions, and new health care technologies and strategies.

Systematic reviews are the building blocks underlying evidence-based practice; they focus attention on the strength and limits of evidence from research studies about the effectiveness and safety of a clinical intervention. In the context of developing recommendations for practice, systematic reviews can help clarify whether assertions about the value of the intervention are based on strong evidence from clinical studies. For more information about AHRQ EPC systematic reviews, see [www.effectivehealthcare.ahrq.gov/reference/purpose.cfm](http://www.effectivehealthcare.ahrq.gov/reference/purpose.cfm).

AHRQ expects that these systematic reviews will be helpful to health plans, providers, purchasers, government programs, and the health care system as a whole. Transparency and stakeholder input are essential to the Effective Health Care Program. Please visit the Web site ([www.effectivehealthcare.ahrq.gov](http://www.effectivehealthcare.ahrq.gov)) to see draft research questions and reports or to join an email list to learn about new program products and opportunities for input.

We welcome comments on this systematic review. They may be sent by mail to the Task Order Officer named below at: Agency for Healthcare Research and Quality, 540 Gaither Road, Rockville, MD 20850, or by email to [epc@ahrq.hhs.gov](mailto:epc@ahrq.hhs.gov).

## Acknowledgments

The authors gratefully acknowledge the following individuals for their contributions to this project: Andrew Hamilton, M.L.S., for assistance with literature search strategy development; Leah Williams, B.S., for editorial support; William Lawrence, M.D., M.S., for his support and guidance in developing this report; and our Associate Editor, Issa Dahabreh, for his review of this report.

## Key Informants

In designing the study questions, the EPC consulted several Key Informants who represent the end-users of research. The EPC sought the Key Informant input on the priority areas for research and synthesis. Key Informants are not involved in the analysis of the evidence or the writing of the report. Therefore, in the end, study questions, design, methodological approaches, and/or conclusions do not necessarily represent the views of individual Key Informants.

Key Informants must disclose any financial conflicts of interest greater than \$10,000 and any other relevant business or professional conflicts of interest. Because of their role as end-users, individuals with potential conflicts may be retained. The TOO and the EPC work to balance, manage, or mitigate any conflicts of interest.

The list of Key Informants who participated in developing this report follows:

Sam S. Chang, M.D., FACS  
Vanderbilt University Medical Center  
Vanderbilt-Ingram Cancer Center  
Nashville, TN

Yair Lotan, M.D.  
University of Texas Southwestern Medical  
Center  
Dallas, TX

Michael O'Donnell, M.D., FACS  
University of Iowa  
Iowa City, IA

Yuval Raizen, M.D.

John Yao, M.D., M.B.A., M.P.H., M.P.P.,  
FACP  
Blue Shield  
San Francisco, CA

## Technical Expert Panel

In designing the study questions and methodology at the outset of this report, the EPC consulted several technical and content experts. Broad expertise and perspectives were sought. Divergent and conflicted opinions are common and perceived as healthy scientific discourse that results in a thoughtful, relevant systematic review. Therefore, in the end, study questions, design, methodologic approaches, and/or conclusions do not necessarily represent the views of individual technical and content experts.

Technical Experts must disclose any financial conflicts of interest greater than \$10,000 and any other relevant business or professional conflicts of interest. Because of their unique clinical or content expertise, individuals with potential conflicts may be retained. The TOO and the EPC work to balance, manage, or mitigate any potential conflicts of interest identified.

The list of Technical Experts who participated in developing this report follows:

Karim Chamie, M.D., M.S.H.S.  
University of California, Los Angeles  
Los Angeles, CA

Sam S. Chang, M.D., FACS  
Vanderbilt University Medical Center  
Vanderbilt-Ingram Cancer Center  
Nashville, TN

Yair Lotan, M.D.  
University of Texas Southwestern Medical  
Center  
Dallas, TX

Raj Pruthi, M.D., FACS  
University of North Carolina School of  
Medicine  
Chapel Hill, NC

Howard Sandler, M.D., M.S., FASTRO  
Cedars-Sinai Medical Center  
Los Angeles, CA

Seth Strobe, M.D., M.P.H.  
Washington University School of Medicine  
St. Louis, MO

Yu-Ning Wong, M.D., M.S.C.E.  
Fox Chase Cancer Center  
Philadelphia, PA

## Peer Reviewers

Prior to publication of the final evidence report, EPCs sought input from independent Peer Reviewers without financial conflicts of interest. However, the conclusions and synthesis of the scientific literature presented in this report do not necessarily represent the views of individual reviewers.

Peer Reviewers must disclose any financial conflicts of interest greater than \$10,000 and any other relevant business or professional conflicts of interest. Because of their unique clinical or content expertise, individuals with potential nonfinancial conflicts may be retained. The TOO and the EPC work to balance, manage, or mitigate any potential nonfinancial conflicts of interest identified.

The list of Peer Reviewers who participated in reviewing this report follows:

M. Craig Hall, M.D., FACS  
High Point Regional Hospital  
High Point, NC

John Seigne, M.D.  
Dartmouth Hitchcock Medical Center  
Lebanon, NH

Michael Koch, M.D.  
Indiana University School of Medicine  
Indianapolis, IN

Angela Smith, M.D., M.S.  
University of North Carolina  
Chapel Hill, NC

Seth P. Lerner, M.D., FACS  
Baylor College of Medicine  
Houston, Texas

# Emerging Approaches to Diagnosis and Treatment of Non–Muscle-Invasive Bladder Cancer

## Structured Abstract

**Objectives.** Non–muscle-invasive bladder cancer (NMIBC) frequently recurs and can progress to muscle-invasive disease. This report reviews the current evidence on emerging approaches to diagnosing and treating bladder cancer.

**Data sources.** Electronic databases (Ovid MEDLINE®, January 1990–October 2014, Cochrane Central Register of Controlled Trials through September 2014, Cochrane Database of Systematic Reviews through September 2014, Health Technology Assessment through Third Quarter 2014, National Health Sciences Economic Evaluation Database through Third Quarter 2014, and Database of Abstracts of Reviews of Effects through Third Quarter 2014); reference lists; and clinical trials registries.

**Review methods.** Using predefined criteria, we selected studies on diagnostic accuracy of urinary biomarkers versus cystoscopy, and trials of fluorescent cystoscopy, intravesical therapy, and radiation therapy for NMIBC that evaluated bladder cancer recurrence, progression, mortality, or harms. The quality of included studies was assessed, data were extracted, and results were summarized qualitatively and using meta-analysis.

**Results.** Urinary biomarkers were associated with sensitivity for bladder cancer that ranged from 0.57 to 0.82 and specificity from 0.74 to 0.88, for positive likelihood ratios from 2.52 to 5.53 and negative likelihood ratios from 0.21 to 0.48 (strength of evidence [SOE]: moderate for quantitative nuclear matrix protein 22 [NMP22], qualitative bladder tumor antigen [BTA], fluorescence in situ hybridization [FISH], and ImmunoCyt™; low for other biomarkers). Sensitivity increased for higher stage and grade tumors. Studies that directly compared the accuracy of quantitative NMP22 and qualitative BTA found no differences in diagnostic accuracy (SOE: moderate).

Most trials found fluorescent cystoscopy to be associated with decreased risk of subsequent bladder recurrence versus white light cystoscopy, but results were inconsistent, and there was no difference in risk of progression or mortality (SOE: low).

Intravesical therapy was more effective than no intravesical therapy for reducing risk of bladder cancer recurrence (for bacillus Calmette-Guérin [BCG], relative risk [RR], 0.56; 95% confidence interval [CI], 0.43 to 0.71; SOE: moderate; for mitomycin C [MMC], doxorubicin, and epirubicin, RR, 0.66 to 0.72; SOE: moderate). BCG was also associated with decreased risk of bladder cancer progression, but no intravesical agent was associated with decreased risk of all-cause or bladder cancer mortality. Intravesical therapy appeared to be effective across subgroups defined by tumor stage, grade, multiplicity, recurrence status, and size (SOE: low). Evidence was too limited to draw strong conclusions regarding effects of dose or duration of therapy on effectiveness. Compared with no intravesical therapy, BCG was associated with a higher rate of local and systemic adverse events (granulomatous cystitis or irritative symptoms in 27% to 84% of patients, macroscopic hematuria in 21% to 72%, and fever in 27% to 44%) (SOE: low). Compared with MMC, BCG was also associated with an increased risk of local adverse events

and fever (SOE: low). One randomized trial found no difference between radiation therapy and no radiation therapy in clinical outcomes in patients with T1G3 cancers.

**Conclusions.** Urinary biomarkers miss a substantial proportion of patients with bladder cancer, and additional research is needed to clarify advantages of fluorescent cystoscopy over white light cystoscopy. Intravesical therapy reduces risk of bladder cancer recurrence versus no intravesical therapy. BCG is the only intravesical therapy shown to be associated with decreased risk of bladder cancer progression, but it is associated with a high rate of adverse events. More research is needed to define optimal doses and regimens of intravesical therapy.

**November 2016 update:** An addendum is located at the end of the main report, before the appendixes.

<b>Executive Summary</b> .....	ES-1
<b>Introduction</b> .....	1
Background .....	1
Nature and Burden of Non–Muscle-Invasive Bladder Cancer .....	1
Diagnosis and Surveillance of Bladder Cancer .....	2
Interventions and Outcomes For Non–Muscle-Invasive Bladder Cancer .....	3
Rationale for Evidence Review .....	4
Scope of Review and Key Questions .....	4
<b>Methods</b> .....	8
Topic Development and Refinement .....	8
Searching for the Evidence .....	8
Study Selection .....	9
Population and Condition of Interest .....	9
Interventions, Comparisons, and Study Designs of Interest .....	9
Outcomes of Interest .....	10
Timing and Setting of Interest .....	10
Data Extraction and Data Management .....	10
Assessment of the Risk of Bias of Individual Studies .....	11
Assessing Applicability .....	12
Data Synthesis .....	12
Grading the Strength of Evidence for Each Key Question .....	13
Peer Review and Public Commentary .....	13
<b>Results</b> .....	15
Results of Literature Searches .....	15
Key Question 1. What is the diagnostic accuracy of various urinary biomarkers compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging) in (1) people with signs or symptoms warranting evaluation for possible bladder cancer or (2) people undergoing surveillance for previously treated bladder cancer? .....	16
Key Points .....	16
Detailed Synthesis .....	17
Key Question 1a. Does the diagnostic accuracy differ according to patient characteristics (e.g., age, sex, race/ethnicity), or according to the nature of the presenting signs or symptoms? .....	26
Key Points .....	26
Detailed Synthesis .....	27
Key Question 2. For patients with non–muscle-invasive bladder cancer, does the use of a formal risk-adapted assessment approach to treatment decisions (e.g., based on Guidelines of the European Association of Urology or on urinary biomarker tests) decrease mortality or improve other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with treatment not guided by a formal assessed risk-adapted approach? .....	28
Key Points .....	28
Detailed Synthesis .....	28

Key Question 3. For patients with non–muscle-invasive bladder cancer treated with transurethral resection of bladder tumor, what is the effectiveness of various intravesical chemotherapeutic or immunotherapeutic agents for decreasing mortality or improving other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with TURBT alone? .....	28
Key Points .....	28
Detailed Synthesis .....	30
Key Question 3a. What is the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents, as monotherapy or in combination? .....	44
Key Points .....	44
Detailed Synthesis .....	47
Key Question 3b. Does the comparative effectiveness differ according to tumor characteristics, such as stage, grade, size, multiplicity, whether the tumor is primary or recurrent, or molecular/genetic markers? .....	69
Key Points .....	69
Detailed Synthesis .....	69
Key Question 3c. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities? .....	70
Key Points .....	70
Key Question 3d. Does the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents differ according to dosing frequency, duration of treatment, and/or the timing of administration relative to TURBT? .....	71
Key Points .....	71
Detailed Synthesis .....	73
Key Question 4. For patients with high-risk non–muscle-invasive bladder cancer treated with TURBT, what is the effectiveness of external beam radiation therapy (either alone or with systemic chemotherapy/immunotherapy) for decreasing mortality or improving other outcomes compared with intravesical chemotherapy/immunotherapy alone or cystectomy? .....	81
Key Points .....	81
Detailed Synthesis .....	81
Key Question 5. In surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of various urinary biomarkers to decrease mortality or improve other outcomes compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging)? .....	82
Key Points .....	82
Detailed Synthesis .....	82
Key Question 5a. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers? .....	82
Key Points .....	82
Key Question 5b. Does the comparative effectiveness differ according to the treatment used (i.e., specific chemotherapeutic or immunotherapeutic agents and/or TURBT)? .....	82
Key Points .....	82
Key Question 5c. Does the comparative effectiveness differ according to the length of surveillance intervals? .....	82

Key Points .....	82
Key Question 5d. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, or race/ethnicity? .....	82
Key Points .....	82
Key Question 6. For initial diagnosis or surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of blue light or other methods of augmented cystoscopy compared with standard cystoscopy for recurrence rates, progression of bladder cancer, mortality, or other clinical outcomes? .....	83
Key Points .....	83
Detailed Synthesis .....	83
Key Question 7. What are the comparative adverse effects of various tests for diagnosis and post-treatment surveillance of bladder cancer, including urinary biomarkers, cytology, and cystoscopy? .....	89
Key Points .....	89
Detailed Synthesis .....	90
Key Question 8. What are the comparative adverse effects of various treatments for non–muscle-invasive bladder cancer, including intravesical chemotherapeutic or immunotherapeutic agents and TURBT? .....	90
Key Points .....	90
Detailed Synthesis .....	93
Key Question 8a. How do adverse effects of treatment vary by patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities such as chronic kidney disease? .....	98
Key Points .....	98
<b>Discussion</b> .....	250

# Executive Summary

## Background

Bladder cancer is the 4th most commonly diagnosed cancer in men and the 10th most commonly diagnosed cancer in women in the United States.<sup>1</sup> The American Cancer Society estimated in 2014 that there would be 74,690 new cases of bladder cancer in the United States that year and about 15,580 deaths due to bladder cancer.<sup>1</sup> Bladder cancer occurs primarily in men age 60 and older, and roughly twice as frequently in white compared with black men.<sup>2</sup> Bladder cancer is an important health problem, with no improvement in associated mortality since 1975.<sup>3</sup> Economic analyses have shown bladder cancer to be the costliest cancer to treat on a per capita basis.<sup>4</sup> The most common risk factor for bladder cancer is cigarette smoking; other risk factors include occupational exposures and family history.

Bladder cancer is staged based on the extent of penetration or invasion into the bladder wall and adjacent structures.<sup>5</sup> Bladder cancers that have not invaded the bladder smooth muscle layer—stage classifications Tis (carcinoma in situ), Ta (noninvasive papillary carcinoma), and T1 (cancer that invades the subepithelial connective tissue) —are broadly grouped as non-muscle-invasive bladder cancer (NMIBC). Stage T2 cancers are muscle invasive, and higher stage cancers invade beyond the muscle layer into surrounding fat (stage classification T3 bladder cancer) or beyond the fat into nearby organs or structures (stage classification T4 bladder cancer). Approximately 75 percent of newly diagnosed bladder cancers are NMIBC.<sup>6</sup> Individuals with NMIBC generally have a good prognosis, with 5-year survival rates higher than 88 percent.<sup>7</sup> However, as many as 70 percent of NMIBC tumors recur after initial treatment, with a 10- to 20-percent risk of progression to invasive bladder cancer.<sup>6</sup> Prognosis is poorer for patients with muscle-invasive bladder cancers (5-year survival rates from 63% to 15%).<sup>7</sup>

A number of tests are available for screening, diagnosis, and staging of bladder cancer. Standard methods for identification of bladder cancer include urine dipstick and microscopic urinalysis (to detect hematuria) and urine cytology (to detect abnormal or cancerous cells in the urine), followed by imaging tests and cystoscopy.<sup>8</sup> Urine-based biomarkers have been developed as potential diagnostic alternatives or supplements to cytology, imaging, and cystoscopy.<sup>9</sup> A number of biomarkers have been evaluated in conjunction with cytology for diagnosis of bladder cancer, potentially reducing the need for cystoscopy. In addition to being performed for initial diagnosis and staging, diagnostic surveillance with cystoscopy and cytology is performed following treatment to identify patients with recurrence or progression of cancer. Urine-based biomarker tests may also be used to help identify recurrence and need for cystoscopy during surveillance.

The large number of available tests and testing strategies, and potential tradeoffs in diagnostic accuracy, risks, and patient preferences pose significant challenges in determining optimal testing and monitoring strategies. Tests with high false-positive rates could lead to unnecessary invasive procedures for further evaluation, and tests with high false-negative rates could lead to missed diagnoses.

Once bladder cancer has been diagnosed, a number of factors affect prognosis and treatment options. These include the stage of the cancer, tumor grade (higher grade tumors are more likely to recur and progress), whether the tumor is an initial tumor or a recurrence, number and size of tumors, and patient's age and general health. The main treatment for NMIBC is local resection with transurethral resection of the bladder tumor (TURBT), often with adjuvant intravesical therapy to destroy residual tumor cells using chemotherapeutic agents (e.g., mitomycin C

[MMC], apaziquone, paclitaxel, gemcitabine, thiotepa, valrubicin, doxorubicin, epirubicin), bacillus Calmette-Guérin (BCG), or interferon immunotherapy.<sup>10</sup> Clinical trials of electromotive drug administration to enhance the effectiveness of intravesical chemotherapy are underway in the United States.

The purpose of this report is to review the currently available evidence on the comparative effectiveness of diagnostic tests and treatments for NMIBC. Although updated guidelines for the treatment and followup of NMIBC from the European Association of Urology were published in 2013,<sup>11</sup> the literature continues to evolve, with much of the new evidence focusing on diagnostic techniques such as fluorescent cystoscopy or urine-based biomarkers and treatments with intravesical therapy alternatives to MMC and BCG. A systematic evidence review that includes recently published research may provide a better understanding of the comparative effectiveness of currently available approaches to diagnosis, treatment, and post-treatment surveillance for NMIBC. The systematic review may be used to update existing clinical recommendations that are several years old or may be out of date because of the development of new technologies and therapies.

## **Scope of Review and Key Questions**

This topic was nominated for review by the American Urological Association and focuses on diagnosis of bladder cancer and treatment of NMIBC. The Key Questions and analytic framework used to guide this report are shown below. The analytic framework (Figure A) shows the scope of this review, including the target population, interventions, comparisons, and health outcomes we examined.

**Key Question 1.** What is the diagnostic accuracy of various urinary biomarkers compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging) in (1) people with signs or symptoms warranting evaluation for possible bladder cancer or (2) people undergoing surveillance for previously treated bladder cancer?

- a. Does the diagnostic accuracy differ according to patient characteristics (e.g., age, sex, race/ethnicity), or according to the nature of the presenting signs or symptoms?

**Key Question 2.** For patients with non–muscle-invasive bladder cancer, does the use of a formal risk-adapted assessment approach to treatment decisions (e.g., based on Guidelines of the European Association of Urology or on urinary biomarker tests) decrease mortality or improve other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with treatment not guided by a formal assessed risk-adapted approach?

**Key Question 3.** For patients with non–muscle-invasive bladder cancer treated with transurethral resection of bladder tumor, what is the effectiveness of various intravesical chemotherapeutic or immunotherapeutic agents for decreasing mortality or improving other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with TURBT alone?

- a. What is the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents, as monotherapy or in combination?
- b. Does the comparative effectiveness differ according to tumor characteristics, such as stage, grade, size, multiplicity, whether the tumor is primary or recurrent, or molecular/genetic markers?
- c. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities?
- d. Does the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents differ according to dosing frequency, duration of treatment, and/or the timing of administration relative to TURBT?

**Key Question 4.** For patients with high-risk non–muscle-invasive bladder cancer treated with TURBT, what is the effectiveness of external beam radiation therapy (either alone or with systemic chemotherapy/immunotherapy) for decreasing mortality or improving other outcomes compared with intravesical chemotherapy/immunotherapy alone or cystectomy?

**Key Question 5.** In surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of various urinary biomarkers to decrease mortality or improve other outcomes compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging)?

- a. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers?
- b. Does the comparative effectiveness differ according to the treatment used (i.e., specific chemotherapeutic or immunotherapeutic agents and/or TURBT)?
- c. Does the comparative effectiveness differ according to the length of surveillance intervals?

- d. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, or race/ethnicity?

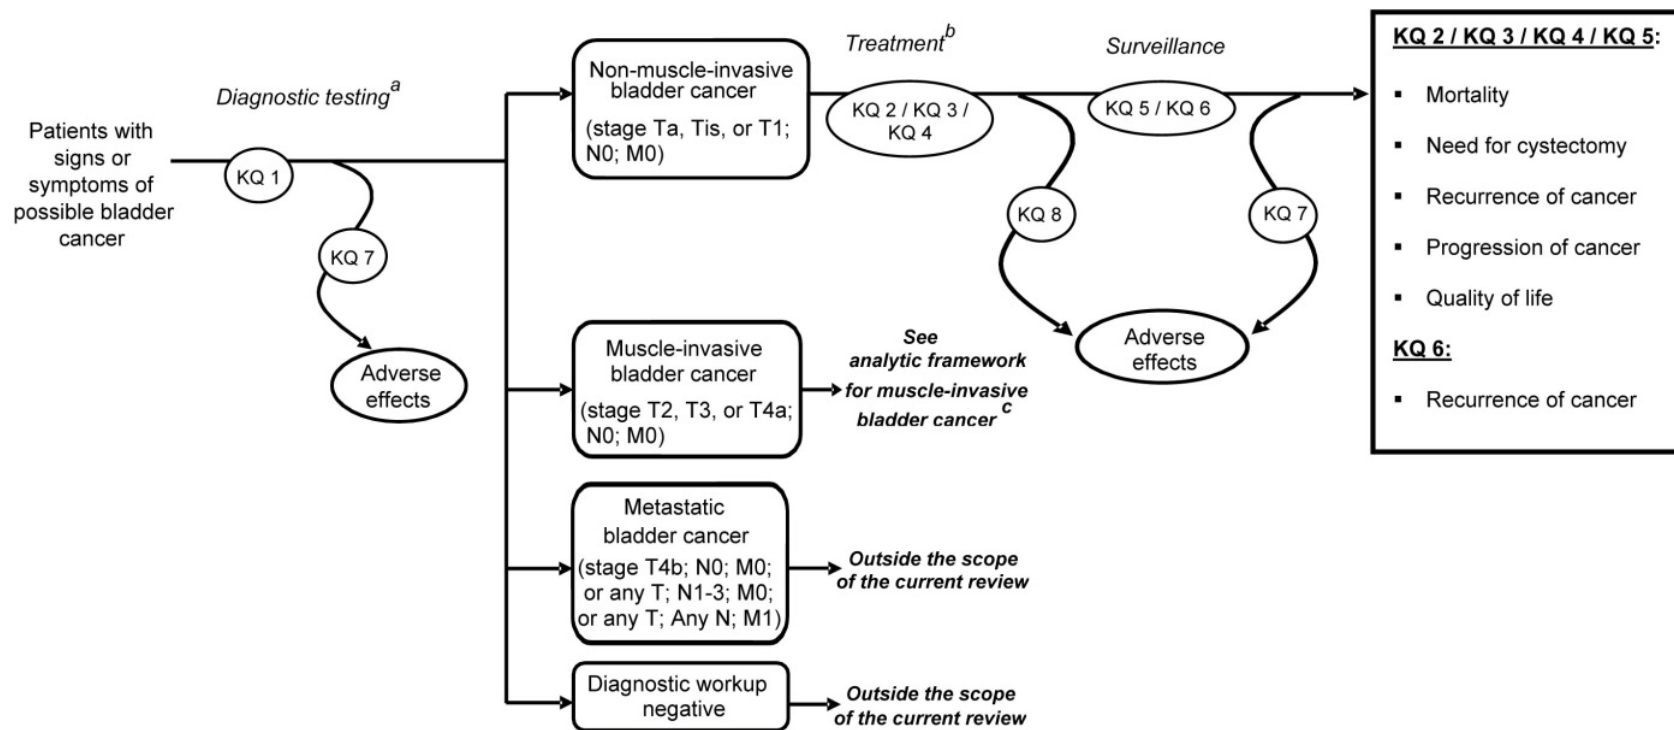

**Key Question 6.** For initial diagnosis or surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of blue light or other methods of augmented cystoscopy compared with standard cystoscopy for recurrence rates, progression of bladder cancer, mortality, or other clinical outcomes?

**Key Question 7.** What are the comparative adverse effects of various tests for diagnosis and post-treatment surveillance of bladder cancer, including urinary biomarkers, cytology, and cystoscopy?

**Key Question 8.** What are the comparative adverse effects of various treatments for non–muscle-invasive bladder cancer, including intravesical chemotherapeutic or immunotherapeutic agents and TURBT?

- a. How do adverse effects of treatment vary by patient characteristics, such as age, sex, ethnicity, performance status, or medical comorbidities such as chronic kidney disease?

**Figure A. Analytic framework**

KQ = Key Question. Cancer stages shown are the TNM (tumor, node, metastasis) classification.

<sup>a</sup>Urinary biomarkers of interest are restricted to tests that are approved for diagnosis of bladder cancer by the U.S. Food and Drug Administration (BTastat<sup>®</sup> [bladder tumor antigen], Alere NMP22<sup>®</sup>, BladderChek<sup>®</sup> [nuclear matrix protein 22], UroVysion<sup>®</sup> [fluorescence in situ hybridization], and ImmunoCyt<sup>™</sup> [immunocytology]) or available in the United States and classified as a Laboratory Developed Test by the Food and Drug Administration (CxBladder<sup>™</sup>).

<sup>b</sup>Chemotherapeutic and immunotherapeutic agents of interest include mitomycin C, apaziquone, paclitaxel, gemcitabine, thiotepa, epirubicin, valrubicin, doxorubicin, bacillus Calmette-Guérin, and interferon.

<sup>c</sup>Muscle-Invasive Bladder Cancer Comparative Effectiveness Review: Chou R, Selph S, Buckley D, et al. Treatment of Nonmetastatic Muscle-Invasive Bladder Cancer.

Comparative Effectiveness Review No. 152. (Prepared by the Pacific Northwest Evidence-based Practice Center under Contract No. 290-2012-00014-1.) AHRQ Publication No. 15-EHC015-EF. Rockville, MD: Agency for Healthcare Research and Quality; June 2015. [www.effectivehealthcare.ahrq.gov/reports/final.cfm](http://www.effectivehealthcare.ahrq.gov/reports/final.cfm).

## Methods

This Comparative Effectiveness Review (CER) follows the methods suggested in the Agency for Healthcare Research and Quality (AHRQ) “Methods Guide for Effectiveness and Comparative Effectiveness Reviews” (AHRQ Methods Guide)<sup>12</sup> and the AHRQ “Methods Guide for Medical Test Reviews.”<sup>13</sup> All methods were determined a priori.

## Searching for the Evidence

A research librarian experienced in conducting literature searches for CERs searched in Ovid MEDLINE® (January 1990–October 2014), Cochrane Central Register of Controlled Trials (through September 2014), Cochrane Database of Systematic Reviews (through September 2014), Health Technology Assessment (through Third Quarter 2014), National Health Sciences Economic Evaluation Database (through Third Quarter 2014), and Database of Abstracts of Reviews of Effects (through Third Quarter 2014) to capture both published and gray literature. We searched for unpublished studies in clinical trial registries (ClinicalTrials.gov, Current Controlled Trials, ClinicalStudyResults.org, and the World Health Organization International Clinical Trials Registry Platform) and regulatory documents (Drugs@FDA.gov and U.S. Food and Drug Administration (FDA) Medical Devices Registration and Listing). Reference lists of relevant studies and previous systematic reviews were hand-searched for additional studies. Scientific information packets were solicited from drug and device manufacturers, and a notice published in the *Federal Register* invited interested parties to submit relevant published and unpublished studies.

## Study Selection

We developed criteria for inclusion and exclusion of studies based on the Key Questions and the defined population, interventions, comparators, outcomes, timing, and settings (PICOTS) and study designs. Inclusion and exclusion criteria are summarized below. Abstracts were reviewed by two investigators, and all citations deemed appropriate for inclusion by at least one of the reviewers were retrieved. Two investigators independently reviewed all full-text articles for inclusion. Discrepancies were resolved by discussion and consensus.

## Population and Condition of Interest

For Key Questions related to diagnosis, we included studies of adults with signs or symptoms of possible bladder cancer (e.g., macroscopic or microscopic hematuria, irritative voiding symptoms) or undergoing surveillance following treatment for bladder cancer. For Key Questions related to treatment, we included adults with NMIBC who were undergoing treatment.

## Interventions, Comparisons, and Study Designs of Interest

We included studies of urinary biomarkers for the diagnosis of bladder cancer approved by the FDA or available in the United States and classified as a Laboratory Developed Test by the FDA (CxBladder™). We excluded studies of diagnostic accuracy of other biomarkers and studies of included biomarkers that did not evaluate diagnostic accuracy of biomarkers against standard diagnostic methods (cystoscopy and histopathology). For cystoscopic methods, we included studies of fluorescent cystoscopy following intravesical instillation of a photosensitizing agent and other methods of augmented cystoscopy (e.g., narrow band imaging)

for the initial diagnosis or surveillance of bladder cancer compared with standard (white light) cystoscopy.

For treatments, we included studies of intravesical therapies (MMC, apaziquone, paclitaxel, gemcitabine, thiotepa, valrubicin, doxorubicin, epirubicin, BCG, and interferon) and external beam radiation therapy with or without systemic chemotherapy or immunotherapy versus TURBT, other intravesical therapies, or cystectomy. We included studies that compared different dosing regimens, different surveillance intervals, and risk-adapted approaches versus other approaches. We also included studies on the effects of patient and tumor characteristics on estimates of effectiveness.

For all Key Questions, we included randomized trials and, when randomized trials were not available, cohort studies with concurrent controls. For diagnostic accuracy, we also included cross-sectional studies. We excluded uncontrolled observational studies, case-control studies, case series, and case reports, as these studies are less informative than studies with a control group.

## **Outcomes of Interest**

For diagnostic accuracy of urinary biomarkers, we evaluated sensitivity, specificity, predictive values, and likelihood ratios, using cystoscopy with biopsy as the reference standard. Clinical outcomes for trials of diagnostic methods and treatments were mortality, need for cystectomy, progression to muscle-invasive bladder cancer, bladder cancer recurrence, and quality of life. We also evaluated adverse effects of diagnostic testing (e.g., false-positives, labeling, anxiety, complications of cystoscopy) and adverse effects of treatment (e.g., cystitis, urinary urgency, urinary frequency, incontinence, hematuria, pain, urosepsis, myelosuppression).

## **Timing and Settings of Interest**

For all Key Questions, we included studies conducted in inpatient or outpatient settings with any duration of followup.

## **Data Extraction and Data Management**

For treatment studies, we extracted the following information into evidence tables: study design; setting; inclusion and exclusion criteria; dose and duration of treatment for experimental and control groups; duration of followup; number of subjects screened, eligible, and enrolled; population characteristics (including age, race/ethnicity, sex, stage of disease, and functional status); results; adverse events; withdrawals due to adverse events; and sources of funding. We calculated relative risks (RRs) and associated 95% confidence intervals (CIs) based on the information provided (sample sizes and incidence of outcomes in each intervention group). We noted discrepancies between calculated and reported results when present.

For diagnostic accuracy studies, we abstracted the following information: setting, screening test or tests, method of data collection, reference standard, inclusion criteria, population characteristics (including age, sex, race/ethnicity, smoking status, signs or symptoms, and prior bladder cancer stage or grade), proportion of individuals with bladder cancer, bladder cancer stage and grade, definition of a positive screening exam, proportion of individuals unexaminable by the screening test, proportion who did not undergo reference standard test, results, and sources of funding. We attempted to create two-by-two tables from information provided (sample size, prevalence, sensitivity, and specificity) and compared calculated measures of diagnostic accuracy based on the two-by-two tables with reported results. We noted

discrepancies between calculated and reported results when present. When reported, we also recorded the area under the receiver operating characteristic curve.<sup>14,15</sup>

Data extraction for each study was completed by one investigator and independently reviewed for accuracy and completeness by a second investigator.

## **Assessment of the Risk of Bias of Individual Studies**

We assessed the risk of bias for randomized trials and observational studies using criteria adapted from those developed by the U.S. Preventive Services Task Force.<sup>16</sup> Studies of diagnostic accuracy were rated using criteria adapted from QUADAS-2, a revised tool for Quality Assessment of Diagnostic Accuracy Studies.<sup>17</sup> These criteria were applied in conjunction with the approaches recommended for medical interventions in the AHRQ Methods Guide<sup>12</sup> and in the AHRQ “Methods Guide for Medical Test Reviews.”<sup>13</sup>

Two investigators independently assessed the risk of bias of each study. Discrepancies were resolved through discussion and consensus. Each study was rated as low, medium, or high risk of bias.<sup>12</sup>

Studies rated low risk of bias were considered to have no more than very minor methodological shortcomings, and their results are likely to be valid. Studies rated moderate risk of bias have some methodological shortcomings, but no flaw or combination of flaws judged likely to cause major bias. The category of moderate risk of bias is broad, and studies with this rating vary in their strengths and weaknesses; the results of some studies assessed to have moderate risk of bias are likely to be valid, while others may be only possibly valid. Studies rated high risk of bias have significant flaws that may invalidate the results. They have a serious or “fatal” flaw or combination of flaws in design, analysis, or reporting; large amounts of missing information; or serious discrepancies in reporting. We did not exclude studies rated as having high risk of bias a priori, but they were considered the least reliable when synthesizing the evidence, particularly when discrepancies between studies were present.

## **Assessing Applicability**

We recorded factors important for understanding the applicability of studies, such as whether the publication adequately described the study sample, the country in which the study was conducted, the characteristics of the patient sample (e.g., age, sex, race/ethnicity, risk factors for bladder cancer, presenting symptoms, and medical comorbidities), tumor characteristics (e.g., stage and grade, primary or recurrent, unifocal or multifocal lesions), the characteristics of the diagnostic tests (e.g., specific test evaluated and cutoffs used) and interventions (e.g., treatment dose, duration, and interval) used, and the magnitude of effects on clinical outcomes.<sup>12</sup> There is no generally accepted universal rating system for applicability, which depends in part on context. Therefore, a rating of applicability (such as high or low) was not assigned because applicability may differ based on the user of this report.

## **Data Synthesis**

For studies on diagnostic accuracy of urinary biomarkers, we performed meta-analyses to help summarize data and obtain more precise estimates.<sup>18</sup> We used a bivariate logistic mixed-effects model<sup>19</sup> to analyze sensitivity and specificity, incorporating the correlation between sensitivity and specificity. We assumed random effects across studies with a bivariate normal distribution for sensitivity and specificity, and heterogeneity among the studies was measured

based on the random-effect variance ( $\tau^2$ ). When few studies were available for an analysis, we used the moment estimates of correlation between sensitivity and specificity in the bivariate model. We calculated positive likelihood ratio and negative likelihood ratio using the summarized sensitivity and specificity.<sup>20,21</sup> For head-to-head comparisons, we used the same bivariate logistic mixed-effects model as described above but added an indicator variable for imaging modalities (equivalent to a meta-regression approach).

All quantitative analyses were conducted using SAS<sup>®</sup> 10.0 (SAS Institute Inc., Cary, NC).<sup>22</sup> We assessed the presence of statistical heterogeneity among the studies using the standard Cochran's chi-square test, and the magnitude of heterogeneity by using the  $I^2$  statistic.<sup>23</sup> When statistical heterogeneity was present, we performed sensitivity analyses by conducting meta-analysis using the profile likelihood method.<sup>24</sup> We also performed sensitivity and subgroup analyses based on ratings for risk of bias, dose of intravesical therapy, inclusion of high-risk patients, and duration of followup. We stratified trials according to the type of instillation regimen, classified as single instillation, induction therapy (treatment for 4 to 8 weeks), maintenance therapy (treatment for longer than 8 weeks), or other. We calculated pooled RRs for the dichotomous outcomes for bladder cancer recurrence, bladder cancer progression, all-cause mortality, bladder cancer mortality, and local and systemic adverse events. Similar analyses were performed for trials of augmented cystoscopy (fluorescent light or narrow band imaging) versus white light cystoscopy.

## **Grading the Strength of Evidence for Each Key Question**

We assessed the strength of evidence (SOE) for each Key Question and outcome using the approach described in the AHRQ Methods Guide,<sup>12</sup> based on the overall quality of each body of evidence; the risk of bias (graded low, moderate, or high); the consistency of results across studies (graded consistent, inconsistent, or unable to determine when only 1 study was available); the directness of the evidence linking the intervention and health outcomes (graded direct or indirect); the precision of the estimate of effect, based on the number and size of studies and CIs for the estimates (graded precise or imprecise); and reporting bias (suspected or undetected)

Assessments of reporting bias were based on whether studies defined and reported primary outcomes, identification of relevant unpublished studies, and when available, by comparing published results with results reported in trial registries.

We graded the SOE for each Key Question using the four categories recommended in the AHRQ Methods Guide.<sup>12</sup> A high grade indicates high confidence that the evidence reflects the true effect and that further research is very unlikely to change our confidence in the estimate of effect. A moderate grade indicates moderate confidence that the evidence reflects the true effect; further research may change our confidence in the estimate of effect and may change the estimate. A low grade indicates low confidence that the evidence reflects the true effect; further research is likely to change the confidence in the estimate of effect and is likely to change the estimate. A grade of insufficient indicates that evidence either is unavailable or is too limited to permit any conclusion because of the availability of only poor-quality studies, extreme inconsistency, or extreme imprecision.

## Results

Database searches resulted in 4,071 potentially relevant articles. After dual review of abstracts and titles, 643 articles were selected for full-text dual review, and 149 studies (in 192 publications) were determined to meet inclusion criteria and were included in this review.

### Key Question 1. Diagnostic Accuracy: Comparison of Urinary Biomarkers

For this Key Question, we included 57 studies (in 60 publications) that evaluated the diagnostic accuracy of urinary biomarkers for diagnosis of bladder cancer.

- Quantitative nuclear matrix protein 22 (NMP22): Sensitivity was 0.69 (95% CI, 0.62 to 0.75) and specificity 0.77 (95% CI, 0.70 to 0.83), based on 19 studies, for a positive likelihood ratio of 3.05 (95% CI, 2.28 to 4.10) and negative likelihood ratio of 0.40 (95% CI, 0.32 to 0.50) (SOE: moderate)
  - For evaluation of symptoms: Sensitivity was 0.67 (95% CI, 0.55 to 0.77; 9 studies) and specificity 0.84 (95% CI, 0.75 to 0.90; 7 studies).
  - For surveillance: Sensitivity was 0.61 (95% CI, 0.49 to 0.71; 10 studies) and specificity 0.71 (95% CI, 0.60 to 0.81; 8 studies).
- Qualitative NMP22: Sensitivity was 0.58 (95% CI, 0.39 to 0.75) and specificity 0.88 (95% CI, 0.78 to 0.94), based on four studies, for a positive likelihood ratio of 4.89 (95% CI, 3.23 to 7.40) and negative likelihood ratio of 0.48 (95% CI, 0.33 to 0.71) (SOE: low).
  - For evaluation of symptoms: Sensitivity was 0.47 (95% CI, 0.33 to 0.61) and specificity 0.93 (95% CI, 0.81 to 0.97), based on two studies.
  - For surveillance: Sensitivity was 0.70 (95% CI, 0.40 to 0.89) and specificity 0.83 (95% CI, 0.75 to 0.89), based on two studies.
- Qualitative bladder tumor antigen (BTA): Sensitivity was 0.64 (95% CI, 0.58 to 0.69; 22 studies) and specificity 0.77 (95% CI, 0.73 to 0.81; 21 studies), for a positive likelihood ratio of 2.80 (95% CI, 2.31 to 3.39) and negative likelihood ratio of 0.47 (95% CI, 0.30 to 0.55) (SOE: moderate).
  - For evaluation of symptoms: Sensitivity was 0.76 (95% CI, 0.67 to 0.83; 8 studies), and specificity 0.78 (95% CI, 0.66 to 0.87; 6 studies).
  - For surveillance: Sensitivity was 0.60 (95% CI, 0.55 to 0.65; 11 studies) and specificity 0.76 (95% CI, 0.69 to 0.83; 8 studies).
- Quantitative BTA: Sensitivity was 0.65 (95% CI, 0.54 to 0.75) and specificity 0.74 (95% CI, 0.64 to 0.82), based on four studies, for a positive likelihood ratio of 2.52 (95% CI, 1.86 to 3.41) and negative likelihood ratio of 0.47 (95% CI, 0.37 to 0.61) (SOE: low).
  - For evaluation of symptoms: Sensitivity was 0.76 (95% CI, 0.61 to 0.87) and specificity 0.53 (95% CI, 0.38 to 0.68), based on one study.
  - For surveillance: Sensitivity was 0.58 (95% CI, 0.46 to 0.69) and specificity 0.79 (95% CI, 0.72 to 0.85), based on two studies.
- Fluorescence in situ hybridization (FISH): Sensitivity was 0.63 (95% CI, 0.50 to 0.75) and specificity 0.87 (95% CI, 0.79 to 0.93), based on 11 studies, for a positive likelihood ratio of 5.02 (95% CI, 2.93 to 8.60) and negative likelihood ratio of 0.42 (95% CI, 0.30 to 0.59) (SOE: moderate).
  - For evaluation of symptoms: Sensitivity was 0.73 (95% CI, 0.50 to 0.88) and specificity 0.95 (95% CI, 0.87 to 0.98), based on two studies, for a positive likelihood

- ratio of 14.2 (95% CI, 5.2 to 39) and negative likelihood ratio of 0.29 (95% CI, 0.14 to 0.60).
- For surveillance: Sensitivity was 0.55 (95% CI, 0.36 to 0.72; 7 studies) and specificity was 0.80 (95% CI, 0.66 to 0.89; 6 studies).
  - ImmunoCyt<sup>™</sup>: Sensitivity was 0.78 (95% CI, 0.68 to 0.85) and specificity 0.78 (95% CI, 0.72 to 0.82), based on 14 studies, for a positive likelihood ratio of 3.49 (95% CI, 2.82 to 4.32) and negative likelihood ratio of 0.29 (95% CI, 0.20 to 0.41) (SOE: moderate).
    - For evaluation of symptoms: Sensitivity was 0.85 (95% CI, 0.78 to 0.90; 6 studies) and specificity 0.83 (95% CI, 0.77 to 0.87; 7 studies).
    - For surveillance: Sensitivity was 0.75 (95% CI, 0.64 to 0.83; 7 studies) and specificity 0.76 (95% CI, 0.70 to 0.81; 8 studies).
  - CxBladder: Sensitivity was 0.82 (95% CI, 0.70 to 0.90) and specificity 0.85 (95% CI, 0.81 to 0.88) for evaluation of symptoms, based on one study, for a positive likelihood ratio of 5.53 (95% CI, 4.28 to 7.15) and negative likelihood ratio of 0.21 (95% CI, 0.13 to 0.36) (SOE: low).
  - Direct (within-study) comparisons:
    - There was no difference between quantitative NMP22 (cutoff >10 U/mL) versus qualitative BTA in sensitivity (0.69 [95% CI, 0.62 to 0.76] vs. 0.66 [95% CI, 0.59 to 0.73], for a difference of 0.03 [95% CI, -0.04 to 0.10]) or specificity (0.73 [95% CI, 0.62 to 0.82] vs. 0.76 [95% CI, 0.66 to 0.84], for a difference of 0.03 [95% CI, -0.08 to 0.01]), based on seven studies (SOE: moderate).
    - ImmunoCyt was associated with higher sensitivity than FISH (0.71 [95% CI, 0.54 to 0.84] vs. 0.61 [95% CI, 0.43 to 0.76], for a difference of 0.11 [95% CI, 0.001 to 0.21]) but lower specificity (0.71 [95% CI, 0.62 to 0.79] vs. 0.79 [95% CI, 0.71 to 0.85], for a difference of -0.08 [95% CI, -0.15 to -0.001]), based on three studies (SOE: low).
    - Evidence for other head-to-head comparisons of urinary biomarkers was based on small numbers of studies with imprecise estimates and methodological shortcomings, precluding reliable conclusions regarding comparative test performance (SOE: insufficient).
    - Sixteen studies found sensitivity of various urinary biomarkers plus cytology to be associated with higher sensitivity than the urinary biomarker alone (0.8 [95% CI, 0.75 to 0.86] vs. 0.69 [95% CI, 0.61 to 0.76], for a difference of 0.13 [95% CI, 0.08 to 0.17]), with no difference in specificity (SOE: moderate).

## Key Question 1a. Diagnostic Accuracy: Patient Characteristics or Presenting Signs or Symptoms

For this Key Question, we included 42 studies that evaluated diagnostic accuracy according to patient characteristics or the nature of the presenting signs or symptoms.

- Effects of tumor stage: Across urinary biomarkers, sensitivity increased with higher tumor stage. Evidence was most robust for quantitative NMP22 (11 studies), qualitative BTA (18 studies), and FISH (8 studies); the association between higher tumor stage and increased sensitivity was least pronounced for ImmunoCyt (10 studies). Sensitivity for carcinoma in situ (CIS) tumors was generally similar to or slightly lower than for T1 tumors (SOE: high).

- Effects of tumor grade: Across urinary biomarkers, sensitivity increased with higher tumor grade. Evidence was most robust for quantitative NMP22 (12 studies), ImmunoCyt (10 studies), qualitative BTA (18 studies), and FISH (9 studies) (SOE: high).
- Effects of tumor size: Two studies found that sensitivity was higher for larger (>1 cm or >2 cm) versus smaller tumors (SOE: low).
- Evidence on the effects of patient characteristics, such as age, sex, smoking status, and presence of other clinical conditions, on diagnostic accuracy of urinary biomarkers was limited and did not clearly or consistently indicate effects on sensitivity or specificity (SOE: low).

## Key Question 2. Use of Formal Risk-Adapted Assessment Approach

This Key Question addresses the issue of whether use of a formal risk-adapted assessment approach to treatment decisions decreases mortality or improves other outcomes compared with treatment not guided by a formal risk-adapted assessment approach.

- No study compared clinical outcomes associated with use of a formal risk-adapted approach to guide treatment of NMIBC versus treatment not guided by a risk-adapted approach (SOE: insufficient).

## Key Question 3. Effect of TURBT Plus Intravesical Therapy Versus TURBT Alone

This Key Question addresses the issue of whether the use of various intravesical chemotherapeutic or immunotherapeutic agents in addition to TURBT decreases mortality or improves other outcomes compared with TURBT alone. We included 37 studies (in 46 publications) that evaluated intravesical therapy versus no intravesical therapy.

- **BCG** was associated with decreased risk of bladder cancer recurrence (3 trials; RR, 0.56; 95% CI, 0.43 to 0.71;  $I^2 = 0\%$ ) and progression (4 trials; RR, 0.39; 95% CI, 0.24 to 0.64;  $I^2 = 40\%$ ) versus no intravesical therapy. No trial evaluated effects of BCG versus no intravesical therapy on risk of all-cause mortality. One trial found BCG to be associated with decreased risk of bladder cancer mortality, but the difference was not statistically significant (RR, 0.62; 95% CI, 0.32 to 1.19) (SOE: insufficient for all-cause and bladder cancer mortality; low for recurrence and progression).
- **MMC** was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (8 trials; RR, 0.71; 95% CI, 0.57 to 0.89;  $I^2 = 72\%$ ), but there was no difference in risk of all cause-mortality (1 trial; hazard ratio [HR], 1.17; 95% CI, 0.89 to 1.53), and effects on bladder cancer mortality (1 trial; HR, 0.71; 95% CI, 0.34 to 1.46) and bladder cancer progression (5 trials; RR, 0.68; 95% CI, 0.39 to 1.20,  $I^2 = 0\%$ ) were not statistically significant (SOE: moderate for recurrence; low for progression, all-cause mortality, and bladder cancer-specific mortality).
- **Doxorubicin** was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (10 trials; RR, 0.80; 95% CI, 0.72 to 0.88;  $I^2 = 46\%$ ), no difference in risk of bladder cancer progression (5 trials; RR, 1.03; 95% CI, 0.72 to 1.46;  $I^2 = 0\%$ ), and no clear effects on all-cause mortality (2 trials) or bladder cancer-specific mortality (1 trial) (SOE: moderate for recurrence; low for progression, all-cause mortality, and bladder cancer-specific mortality).

- **Epirubicin** was associated with decreased risk of bladder cancer recurrence (9 trials; RR, 0.63; 95% CI, 0.53 to 0.75;  $I^2 = 64\%$ ) (SOE: moderate), but the effect on bladder cancer progression was not statistically significant (8 trials; RR, 0.79; 95% CI, 0.84 to 1.30;  $I^2 = 27\%$ ) (SOE: low).
- **Gemcitabine** was examined in one trial that found no difference between single-instillation gemcitabine versus no intravesical therapy in risk of bladder cancer recurrence (RR, 0.98; 95% CI, 0.70 to 1.36); estimates for progression (RR, 3.00; 95% CI, 0.32 to 28.4), all-cause mortality (RR, 0.50; 95% CI, 0.13 to 2.00), and bladder cancer-specific mortality (RR, 1.00; 95% CI, 0.06 to 15.81) were very imprecise (SOE: low for bladder cancer recurrence; insufficient for all-cause and bladder cancer-specific mortality and progression).
- **Interferon alpha** was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy that was not statistically significant (3 trials; RR, 0.75; 95% CI, 0.53 to 1.06;  $I^2 = 50\%$ ), decreased risk of bladder cancer progression (2 trials; RR, 0.33; 95% CI, 0.14 to 0.76;  $I^2 = 0\%$ ), and no difference in risk of bladder cancer-specific mortality (1 trial; RR, 1.00; 95% CI, 0.15 to 6.75) (SOE: low).
- **Interferon gamma** was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (1 trial; RR, 0.72; 95% CI, 0.51 to 1.01), with no difference in risk of bladder cancer progression (1 trial; RR, 1.08; 95% CI, 0.07 to 16.4) (SOE: low).
- **Thiotepa** was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy that was not statistically significant (5 trials; RR, 0.78; 95% CI, 0.58 to 1.06;  $I^2 = 69\%$ ), with insufficient evidence to determine effects on progression or mortality (SOE: low for recurrence, insufficient for all-cause and bladder cancer mortality and progression).

### Key Question 3a. Comparative Effectiveness: Chemotherapeutic or Immunotherapeutic Agents as Monotherapy or in Combination

For this Key Question, we included 54 studies in 66 publications.

#### BCG Versus MMC

- There were no differences between BCG and MMC in risk of bladder cancer recurrence (10 trials; RR, 0.95; 95% CI, 0.81 to 1.11;  $I^2 = 67\%$ ), but BCG was associated with decreased risk in the subgroup of trials that evaluated maintenance regimens (5 trials; RR, 0.79; 95% CI, 0.71 to 0.87;  $I^2 = 0\%$ ). There was no difference in risk of all-cause (7 trials; RR, 0.94; 95% CI, 0.83 to 1.06;  $I^2 = 0\%$ ) or bladder cancer-specific mortality (5 trials; RR, 0.77; 95% CI, 0.54 to 1.10;  $I^2 = 0\%$ ) or progression (7 trials; RR, 0.88; 95% CI, 0.66 to 1.17;  $I^2 = 18\%$ ) (SOE: moderate for all-cause mortality, bladder cancer-specific mortality, and progression; low for recurrence).
- There were no differences between BCG alone and BCG plus MMC given sequentially in risk of all-cause (1 trial; RR, 1.57; 95% CI, 0.67 to 3.71) or bladder cancer-specific mortality (2 trials; RR, 1.10; 95% CI, 0.50 to 2.38;  $I^2 = 17\%$ ), bladder cancer recurrence (4 trials; RR, 1.03; 95% CI, 0.70 to 1.52;  $I^2 = 75\%$ ), progression (3 trials; RR, 0.87; 95% CI, 0.40 to 1.91;  $I^2 = 22\%$ ), or cystectomy (4 trials; RR, 0.87; 95% CI, 0.41 to 1.84;  $I^2 = 0\%$ ) (SOE: low).

- There were no differences between BCG plus MMC administered sequentially and MMC alone in risk of all-cause (2 trials; RR, 1.53; 95% CI, 0.72 to 1.74 and RR 0.95; 95% CI, 0.71 to 1.30) or bladder cancer–specific mortality (2 trials; RR, 0.64; 95% CI, 0.22 to BCG 1.88 and RR, 0.95; 95% CI, 0.45 to 1.56), bladder cancer recurrence (2 trials; RR, 0.88; 95% CI, 0.75 to 1.03;  $I^2 = 0\%$ ), or progression (2 trials; RR, 0.82; 95% CI, 0.40 to 1.68 and RR, 1.28; 95% CI, 0.35 to 4.61) (SOE: low).

## BCG Versus Doxorubicin

- BCG was associated with decreased risk of bladder cancer recurrence versus doxorubicin (2 trials; RR, 0.31; 95% CI, 0.16 to 0.61 and RR, 0.75; 95% CI, 0.64 to 0.88), but there were no differences in risk of all-cause mortality (2 trials; RR, 0.40; 95% CI, 0.01 to 12 and RR, 1.00; 95% CI, 0.71 to 1.37) or bladder cancer progression (1 trial; RR, 0.20; 95% CI, 0.02 to 1.72) (SOE: low).

## BCG Versus Epirubicin

- BCG was associated with reduced risk of bladder cancer recurrence versus epirubicin, but statistical heterogeneity was high (5 trials; RR, 0.54; 95% CI, 0.40 to 0.74;  $I^2 = 76\%$ ). Estimates favored BCG for all-cause (3 trials; RR, 0.72; 95% CI, 0.44 to 1.19;  $I^2 = 87\%$ ) and bladder cancer–specific mortality (3 trials; RR, 0.72; 95% CI, 0.25 to 2.08;  $I^2 = 80\%$ ) and bladder cancer progression (5 trials; RR, 0.60; 95% CI, 0.36 to 1.01;  $I^2 = 47\%$ ), but differences were not statistically significant (SOE: moderate for recurrence; low for all-cause mortality, bladder cancer–specific mortality, and progression).
- There was no difference between BCG alone and BCG plus epirubicin administered sequentially in risk of bladder cancer recurrence (3 trials; RR, 1.25; 95% CI, 0.92 to 1.69;  $I^2 = 0\%$ ). BCG alone was associated with increased risk of bladder cancer progression (3 trials; RR, 1.92; 95% CI, 0.73 to 5.07;  $I^2 = 0\%$ ), but the difference was not statistically significant (SOE: low).
- One trial found no differences between BCG alone and epirubicin plus interferon alpha-2b in risk of bladder cancer–specific mortality (RR, 0.79; 95% CI, 0.32 to 1.63) or progression-free survival, although BCG was associated with decreased risk of bladder cancer recurrence (RR, 0.66; 95% CI, 0.51 to 0.85) (SOE: low).

## BCG Versus Gemcitabine

- There were no differences between BCG and gemcitabine in risk of all-cause mortality (1 trial; RR, 1.20; 95% CI, 0.04 to 34), progression (2 trials; RR, 1.11; 95% CI, 0.53 to 2.34 and RR, 0.52; 95% CI, 0.13 to 2.06), or quality of life (1 trial) (SOE: low).
- Evidence from three trials was insufficient to determine effects of BCG versus gemcitabine on risk of bladder cancer recurrence because of clinical heterogeneity and inconsistent findings (RR, 1.67 [95% CI, 1.21 to 2.29]; RR, 0.53 [95% CI, 0.28 to 1.01]; and RR, 0.76 [95% CI, 0.44 to 1.90]) (SOE: insufficient).
- There were no differences between BCG alone and BCG plus gemcitabine administered sequentially in risk of bladder cancer recurrence (1 trial; RR, 0.86; 95% CI, 0.49 to 1.51) or progression (1 trial; RR, 1.18; 95% CI, 0.30 to 4.61) (SOE: low).

## **BCG Versus Interferon**

- BCG was associated with reduced risk of bladder cancer recurrence versus interferon alpha-2a (1 trial; RR, 0.57; 95% CI, 0.39 to 0.82), but the difference in risk of bladder cancer progression was not statistically significant (1 trial; RR, 0.69; 95% CI, 0.25 to 1.92) (SOE: low).
- In patients pretreated with MMC, BCG alone was associated with reduced risk of bladder cancer recurrence versus alternating BCG plus interferon alpha-2b (1 trial; RR, 0.42; 95% CI, 0.30 to 0.59) (SOE: low).
- Differences between BCG alone and coadministration of BCG and interferon alpha-2b in risk of bladder cancer recurrence (1 trial; RR, 0.88; 95% CI, 0.71 to 1.08) or progression (1 trial; RR, 0.76; 95% CI, 0.17 to 3.30) did not reach statistical significance (SOE: low).

## **BCG Versus Thiotepa**

- Two trials found that, for maintenance therapy, BCG was associated with decreased risk of recurrence versus thiotepa (RR, 0.38 [95% CI, 0.19 to 0.76] and RR, 0.04 [95% CI, 0.00 to 0.63]), but estimates for other outcomes were too imprecise to evaluate effects (SOE: low for recurrence; insufficient for progression, death, and cystectomy).

## **MMC Versus Doxorubicin**

- There was no difference between MMC and doxorubicin in risk of bladder cancer recurrence (6 trials; RR, 1.00; 95% CI, 0.82 to 1.22;  $I^2 = 44\%$ ), but MMC was associated with a non-statistically significant trend toward decreased risk of bladder cancer progression (4 trials; RR, 0.63; 95% CI, 0.37 to 1.08;  $I^2 = 21\%$ ) (SOE: low).

## **MMC Versus Epirubicin**

- There was no difference between MMC and epirubicin in risk of bladder cancer recurrence in one trial (RR, 1.16; 95% CI, 0.52 to 2.58) (SOE: low).

## **MMC Versus Gemcitabine**

- In one trial, MMC was associated with no difference in risk of bladder cancer progression compared with gemcitabine ( $p = 0.29$ ). MMC was associated with increased risk of recurrence, but the difference was not statistically significant (RR, 1.64; 95% CI, 0.64 to 4.19) (SOE: low).

## **MMC Versus Interferon Alpha**

- One trial found no difference between MMC and interferon alpha in risk of bladder cancer recurrence (RR, 0.77; 95% CI, 0.58 to 1.01) or bladder cancer progression (RR, 1.38; 95% CI, 0.49 to 3.88) (SOE: low).

## **MMC Versus Interferon Gamma**

- MMC was associated with increased risk of bladder cancer recurrence versus interferon gamma in one trial (RR, 1.61; 95% CI, 0.97 to 2.67) (SOE: low).

### **MMC Versus Thiotepa**

- Two trials found no difference between MMC and thiotepa in risk of recurrence (RR, 1.76 [95% CI, 0.36 to 8.70] and RR, 1.14 [95% CI, 0.60 to 2.16]) (SOE: low).

### **Doxorubicin Versus Epirubicin**

- Doxorubicin was associated with increased risk of bladder cancer recurrence versus epirubicin (3 trials; RR, 1.56; 95% CI, 1.08 to 2.22;  $I^2 = 0\%$ ); the difference in risk of progression was not statistically significant (1 trial; RR, 1.32; 95% CI, 0.50 to 3.47) (SOE: low).

### **Doxorubicin Versus Thiotepa**

- There was no statistically significant difference between doxorubicin and thiotepa in risk of bladder cancer recurrence (RR, 1.22; 95% CI, 0.76 to 1.94). Estimates from one trial for progression (RR, 2.11; 95% CI, 0.40 to 11.06), noncancer mortality (RR, 0.35; 95% CI, 0.01 to 8.45), and cancer-specific mortality (RR, 3.17; 95% CI, 0.13 to 76.1) were very imprecise (SOE: low for recurrence; insufficient for progression, noncancer mortality, and cancer-specific mortality).

### **Epirubicin Versus Interferon Alpha**

- Epirubicin was associated with decreased risk of bladder cancer recurrence versus interferon alpha in one trial (RR, 0.67; 95% CI, 0.49 to 0.91) (SOE: low).

## **Key Question 3b. Comparative Effectiveness: Tumor Characteristics**

For this Key Question, we included 29 studies.

- There were no clear differences in estimates of effectiveness of intravesical therapies in subgroups defined by tumor stage, grade, size, multiplicity, recurrence status, or DNA ploidy (SOE: low).

## **Key Question 3c. Comparative Effectiveness: Patient Characteristics**

- No trial evaluated how estimates of effectiveness of intravesical therapy vary in subgroups defined by patient characteristics, such as age, sex, race/ethnicity, performance status, and comorbidities (SOE: insufficient).
- In patients with recurrence or progression following prior BCG therapy, one trial found maintenance therapy with gemcitabine to be associated with decreased risk of recurrence versus repeat treatment with BCG, and one trial found MMC maintenance therapy to be associated with lower likelihood of disease-free survival than gemcitabine; estimates for progression were imprecise (SOE: low).

### **Key Question 3d. Comparative Effectiveness: Dosing Frequency, Treatment Duration, Timing**

For this Key Question, we included 53 studies (in 57 publications) that compared different doses or instillation regimens of the same drug or different BCG strains.

#### **BCG**

- Six trials found no clear differences between standard and lower doses of BCG in risk of recurrence, progression, or bladder cancer–specific mortality, including in patients with higher risk NMIBC, although there was some inconsistency between trials. Standard therapy was associated with increased risk of local and systemic adverse events versus lower dose BCG in most trials (SOE: low).
- Three trials of responders to BCG induction therapy found no clear differences between maintenance therapy versus no maintenance therapy in risk of all-cause mortality (3 trials; RR, 0.90; 95% CI, 0.72 to 1.11) or bladder cancer–specific mortality (2 trials; RR, 1.14; 95% CI, 0.24 to 5.40), although maintenance therapy was associated with decreased risk of recurrence (RR, 0.76 [95% CI, 0.65 to 0.88] and RR, 0.16 [95% CI, 0.02 to 1.21]) (SOE: low).
- Two of three trials found that more prolonged courses of BCG were associated with decreased risk of bladder cancer recurrence versus induction therapy in patients with higher risk NMIBC, but increased risk of adverse events (SOE: low).
- One trial found OncoTICE® strain BCG to be associated with lower likelihood of 5-year recurrence-free survival than BCG Connaught (48% vs. 74%;  $p = 0.01$ ), and one trial found OncoTICE strain BCG to be associated with lower likelihood of 5-year recurrence-free survival than RIVM strain BCG (36% vs. 54%;  $p = 0.07$ ). Four trials that compared non-OncoTICE BCG strains found no differences (SOE: low).

#### **MMC**

- One trial of patients with NMIBC (not selected for being at higher risk) found no clear differences between MMC 40 mg single instillation and MMC 40 mg five instillations in risk of recurrence, progression, or mortality. The single instillation was associated with lower risk of local adverse events (SOE: low).
- One trial of patients with higher risk NMIBC found that MMC 20 mg induction therapy for 6 weeks was associated with higher risk of recurrence than maintenance therapy. There were no clear differences in risk of adverse events (SOE: low).
- Two trials of MMC maintenance regimens in patients with NMIBC not selected for being at higher risk found some evidence that a higher total number of instillations and increased frequency during initial therapy were associated with lower risk of recurrence and progression, and might be associated with lower risk of local adverse events (SOE: low).
- One trial found no difference between “optimized” (through alkalization of urine) versus nonoptimized administration of intravesical MMC in risk of recurrence in patients with low-risk NMIBC, but one trial of patients with higher risk NMIBC found optimized administration to be associated with lower risk of recurrence and increased risk of local adverse events (SOE: low).

## **Doxorubicin**

- Two trials of patients with NMIBC not selected for being at higher risk found no differences between doxorubicin 30 mg and 20 mg given as short (8 weeks) or long (2 years) regimens in risk of recurrence or progression, with no differences in adverse events (SOE: low).
- Two trials of patients with NMIBC not selected for being at higher risk found no clear differences between doxorubicin induction therapy alone and induction plus maintenance in risk of recurrence, progression, or mortality, with no differences in adverse events (SOE: low).
- Two trials of doxorubicin found no clear benefits associated with administration prior to TURBT or multiple instillations immediately after TURBT, with some evidence of increased adverse events with multiple immediate post-TURBT instillations (SOE: low).

## **Epirubicin**

- Three trials of epirubicin found no clear evidence that higher doses are associated with reduced risk of recurrence or progression versus lower doses, with no differences in adverse events (SOE: moderate).
- Three trials found no clear difference between single-instillation epirubicin and multiple instillations in patients with low- or high-risk NMIBC in risk of recurrence, progression, or bladder cancer-specific mortality, with some evidence of lower risk of local adverse events with single instillation (SOE: moderate).
- Two trials, including one trial of patients with higher risk NMIBC, found no clear differences between epirubicin maintenance therapy and induction without maintenance in risk of recurrence or progression. There were no differences in risk of local adverse events (SOE: moderate).
- Five trials that evaluated different epirubicin regimens that included maintenance therapy found some evidence that more intensive therapy is associated with decreased risk of recurrence, but results were inconsistent. There was no difference in risk of adverse events (SOE: low).

## **Thiotepa**

- Two trials found no clear differences between thiotepa 30 mg and 60 mg for maintenance or for treatment of incompletely resected NMIBC or CIS (SOE: low).

## **Interferon Alpha-2b**

- Four trials found that higher doses of interferon alpha-2b were associated with improved outcomes related to recurrence, progression, or resolution of bladder cancer marker lesions versus lower doses, but most estimates were imprecise and did not reach statistical significance. There were no clear differences in risk of local or systemic adverse events (SOE: low).

## **Multiple Drugs**

- One trial found no difference between initiation of intravesical therapy (9 instillations over 6 months) with MMC or doxorubicin 50 mg on the day of TURBT versus 1 to 2 weeks after TURBT in risk of recurrence, progression, or mortality, or between

maintenance beyond 6 months versus no additional maintenance therapy. There were no clear differences in local or systemic adverse events (SOE: low).

#### **Key Question 4. For TURBT Patients, Effectiveness of Radiation Therapy Versus Intravesical Therapy or Cystectomy**

This Key Question addressed the effectiveness of external beam radiation therapy for decreasing mortality or improving other outcomes compared with intravesical chemotherapy/immunotherapy alone or cystectomy in patients treated with TURBT. One randomized trial (rated moderate risk of bias) compared external beam radiation therapy with no radiation therapy in patients with NMIBC.

- One randomized trial of patients with T1 Grade (G) 3G3 bladder cancer found no effects of radiation therapy versus no radiotherapy (for unifocal disease and no CIS) or radiation therapy versus intravesical therapy (for multifocal disease or CIS) in recurrence-free survival (HR, 0.94; 95% CI, 0.67 to 1.30), progression-free interval (HR, 1.07; 95% CI, 0.65 to 1.74), progression-free survival (HR, 1.35; 95% CI, 0.92 to 1.98), or overall survival (HR, 1.32; 95% CI, 0.86 to 2.04) after 5 years (SOE: low).

#### **Key Question 5. Effectiveness of Urinary Biomarkers Versus Other Urinary Biomarkers or Standard Diagnostic Methods for Surveillance**

- No study evaluated the effectiveness of urinary biomarkers to decrease mortality or improve other outcomes compared with standard diagnostic methods or other urinary biomarkers in surveillance of patients treated for NMIBC.

#### **Key Question 5a. Comparative Effectiveness: Tumor Characteristics**

- No evidence was found (SOE: insufficient).

#### **Key Question 5b. Comparative Effectiveness: Treatment Used**

This Key Question addressed the issue of whether comparative effectiveness differs according to the treatment used (i.e., specific chemotherapeutic or immunotherapeutic agents and/or TURBT).

- No evidence was found (SOE: insufficient).

#### **Key Question 5c. Comparative Effectiveness: Surveillance Intervals**

- No evidence was found (SOE: insufficient).

#### **Key Question 5d. Comparative Effectiveness: Patient Characteristics**

- No evidence was found (SOE: insufficient).

## Key Question 6. Effectiveness of Augmented Versus Standard Cystoscopy

This Key Question addresses the effectiveness of blue light or other methods of augmented cystoscopy compared with standard cystoscopy for recurrence rates, progression of bladder cancer, mortality, or other clinical outcomes in initial diagnosis or surveillance of patients treated for NMIBC. We included 14 trials (in 19 publications) that evaluated clinical outcomes of augmented (fluorescent or narrow band imaging) cystoscopy versus standard white light cystoscopy.

- There was no difference between fluorescent versus white light cystoscopy in risk of mortality (3 trials; RR, 1.28; 95% CI, 0.55 to 2.95;  $I^2 = 41\%$ ) (SOE: low).
- Fluorescent cystoscopy with 5-aminolevulinic acid (5-ALA) or hexaminolevulinate (HAL) was associated with decreased risk of bladder cancer recurrence versus white light cystoscopy at short-term (<3 months; 9 trials; RR, 0.58; 95% CI, 0.36 to 0.94,  $I^2 = 75\%$ ), intermediate-term (3 months to <1 year; 5 trials; RR, 0.67; 95% CI, 0.51 to 0.88;  $I^2 = 35\%$ ), and long-term followup ( $\geq 1$  year; 11 trials; RR, 0.81; 95% CI, 0.68 to 0.98;  $I^2 = 64\%$ ), but findings were inconsistent and potentially susceptible to performance bias (because of failure to blind the initial cystoscopy) and publication bias (SOE: low).
- There was no difference between fluorescent and white light cystoscopy in risk of progression to muscle-invasive bladder cancer (9 trials; RR, 0.78; 95% CI, 0.55 to 1.12;  $I^2 = 0\%$ ) (SOE: moderate).
- Narrow band imaging was associated with lower risk of bladder cancer recurrence at 3 months (3.9% vs. 17%; odds ratio [OR], 0.62; 95% CI, 0.41 to 0.92) and at 12 months (OR, 0.24; 95% CI, 0.07 to 0.81) compared with white light cystoscopy in one trial (SOE: low).

## Key Question 7. Adverse Effects: Tests

We included seven studies that evaluated adverse effects of various tests for diagnosis and post-treatment surveillance of bladder cancer.

- Urinary biomarkers miss 23 to 42 percent of patients with bladder cancer and are incorrectly positive in 11 to 28 percent of patients without bladder cancer, but no study directly measured effects of inaccurate diagnosis on clinical outcomes (SOE: insufficient).
- There were no clear differences between fluorescent cystoscopy and white light cystoscopy in the risk of false-positives in two trials (SOE: low).
- There were no clear differences between fluorescent cystoscopy and white light cystoscopy in the risk of renal and genitourinary adverse events in two trials (SOE: low).

## Key Question 8. Adverse Effects: Treatments

This Key Question addressed adverse effects of various treatments, including intravesical chemotherapeutic or immunotherapeutic agents and TURBT. We included 22 studies of intravesical therapies that reported harms.

## **Intravesical Therapy Versus No Intravesical Therapy**

- Four trials of BCG versus no intravesical therapy reported granulomatous cystitis or irritative symptoms in 27 to 84 percent of patients treated with BCG, macroscopic hematuria in 21 to 72 percent, and fever in 27 to 44 percent. Harms were not reported in patients who did not receive intravesical therapy (SOE: low).
- Evidence on harms associated with non-BCG intravesical therapies versus no intravesical therapy was very limited, although some trials reported an increased risk of local adverse events with intravesical therapies. Evidence was insufficient to determine effects of non-BCG intravesical therapies versus no intravesical therapy on risk of systemic adverse events (SOE: low for local adverse events; insufficient for systemic adverse events).

## **BCG Versus MMC**

- BCG was associated with increased risk of any local adverse event (2 trials; RR, 2.01; 95% CI, 1.59 to 2.54;  $I^2 = 0\%$ ), granulomatous cystitis (5 trials; RR, 1.71; 95% CI, 1.22 to 2.41;  $I^2 = 58\%$ ), dysuria (3 trials; 48% vs. 32%; RR, 1.23; 95% CI, 1.03 to 1.46;  $I^2 = 34\%$ ), and hematuria (6 trials; RR, 1.78; 95% CI, 1.24 to 2.56;  $I^2 = 62\%$ ) versus MMC (SOE: low for local adverse events and dysuria; moderate for granulomatous cystitis and hematuria).
- BCG was associated with increased risk of any systemic adverse event (2 trials; RR, 2.01; 95% CI, 1.59 to 2.54;  $I^2 = 0\%$ ) and fever (4 trials; RR, 4.51; 95% CI, 2.31 to 8.82;  $I^2 = 25\%$ ) versus MMC (SOE: low).
- There was no difference between BCG and MMC in risk of discontinuation of instillations (4 trials; RR, 1.26; 95% CI, 0.39 to 4.01;  $I^2 = 70\%$ ) (SOE: low).
- BCG alone was associated with increased risk of discontinuation of instillations versus BCG plus MMC given sequentially (1 trial; RR, 4.06; 95% CI, 2.09 to 7.86) (SOE: low).

## **BCG Plus MMC Versus MMC**

- There was no difference between sequentially administered BCG plus MMC and MMC alone in local adverse events (1 trial; RR, 1.36; 95% CI, 0.60 to 3.08) or risk of granulomatous cystitis (1 trial; RR, 1.30; 95% CI, 0.88 to 1.93) (SOE: low).
- There was no difference between BCG and MMC given sequentially and MMC used alone in systemic adverse events (1 trial; RR, 1.07; 95% CI, 0.63 to 1.84), but BCG plus MMC was associated with increased risk of fever (1 trial; 12% vs. 3%; RR, 3.75; 95% CI, 1.08 to 13) (SOE: low).
- There was no difference between alternating BCG plus MMC and MMC alone in risk of discontinuation of instillations in patients with CIS (1 trial; RR, 0.54; 95% CI, 0.16 to 1.84) or in patients with Ta or T1 tumors (1 trial; RR, 0.93; 95% CI, 0.52 to 1.65) (SOE: low).

## **BCG Versus Doxorubicin**

- BCG was associated with increased risk of cystitis versus doxorubicin (1 trial; RR, 17; 95% CI, 1 to 289), but there was insufficient evidence to determine effects on dysuria (3 trials; data not pooled) and hematuria (2 trials; data not pooled) because of small numbers of trials with inconsistent results (SOE: low for cystitis; insufficient for dysuria and hematuria).

## BCG Versus Epirubicin

- BCG was associated with increased risk of local side effects (1 trial; RR, 3.28; 95% CI, 1.26 to 8.53), granulomatous cystitis (4 trials; RR, 1.86; 95% CI, 1.35 to 2.56;  $I^2 = 65\%$ ), dysuria (1 trial; RR, 2.43; 95% CI, 1.13 to 5.24), hematuria (4 trials; RR, 1.77; 95% CI, 1.41 to 2.22;  $I^2 = 0\%$ ), and fever (2 trials; RR, 9.73; 95% CI, 2.72 to 35;  $I^2 = 0\%$ ) versus epirubicin alone, but results were mixed for discontinuation of intravesical therapy (2 trials; data not pooled) (SOE: low for local side effects, dysuria, granulomatous cystitis, hematuria, and fever; insufficient for discontinuation of instillations).
- BCG alone was associated with increased risk of systemic adverse events (1 trial; RR, 5.97; 95% CI, 2.18 to 16), granulomatous cystitis (1 trial; RR, 2.28; 95% CI, 1.46 to 3.54), and discontinuation of instillations (1 trial; RR, 4.56; 95% CI, 1.35 to 15) versus sequentially administered BCG and epirubicin, but there was no difference in risk of dysuria (1 trial; RR, 1.22; 95% CI, 0.56 to 2.66), hematuria (2 trials; RR, 2.27; 95% CI, 0.86 to 6.00;  $I^2 = 0\%$ ), or fever (2 trials; RR, 2.09; 95% CI, 0.48 to 9.02;  $I^2 = 0\%$ ) (SOE: low).

## BCG Versus Gemcitabine

- There were no differences between BCG and gemcitabine in risk of local adverse events requiring postponement or discontinuation of intravesical therapy (1 trial; RR, 1.33; 95% CI, 0.32 to 5.49), systemic adverse events (1 trial; RR, 0.50; 95% CI, 0.10 to 2.5), dysuria (2 trials; RR, 1.51; 95% CI, 0.92 to 2.50;  $I^2 = 0\%$ ), or hematuria (2 trials; RR, 4.62; 95% CI, 0.78 to 27;  $I^2 = 29\%$ ), but BCG was associated with increased risk of fever (2 trials; RR, 6.24; 95% CI, 1.03 to 38;  $I^2 = 5\%$ ) (SOE: low).
- One trial found no difference between BCG alone and BCG plus gemcitabine given sequentially in risk of dysuria (RR, 0.92; 95% CI, 0.52 to 1.65) or hematuria (RR, 0.30; 95% CI, 0.08 to 1.09) (SOE: low).

## BCG Versus Interferon

- BCG was associated with increased risk of dysuria versus interferon alpha-2a (1 trial; RR, 84; 95% CI, 5.29 to 1,319) but no difference in risk of fever (1 trial; RR, 4.82; 95% CI, 0.25 to 94) (SOE: low).
- BCG alone was associated with increased risk of constitutional symptoms (1 trial; RR, 1.63; 95% CI, 1.12 to 2.38) and fever (1 trial; RR, 2.26; 95% CI, 1.30 to 3.95) versus coadministration of BCG and interferon alpha-2b (SOE: low).

## BCG Versus Thiotepa

- BCG was associated with increased risk of bladder irritability (1 trial; RR, 2.93; 95% CI, 1.45 to 5.90), cystitis (1 trial; RR, 18; 95% CI, 1.11 to 306), and fever (1 trial; RR, 8.36; 95% CI, 0.47 to 150) versus thiotepa (SOE).

## MMC Versus Doxorubicin

- Evidence was insufficient to determine effects of MMC versus doxorubicin on risk of local adverse events, based on inconsistent results from six trials (SOE: insufficient).

### **MMC Versus Epirubicin**

- One small trial found no difference between MMC and epirubicin 80 mg in risk of urinary symptoms (SOE: low).

### **MMC Versus Interferon Alpha**

- One trial found MMC to be associated with greater risk of hematuria versus interferon alpha (RR, 2.00; 95% CI, 1.09 to 3.65), decreased risk of fever (RR, 0.13; 95% CI, 0.03 to 0.55), and no difference in risk of dysuria or urinary frequency (SOE: low).

### **MMC Versus Gemcitabine**

- One trial found MMC to be associated with increased risk of chemical cystitis versus gemcitabine (RR, 3.93; 95% CI, 1.17 to 13.14), with no difference in risk of dysuria or hematuria (SOE: low).

### **Doxorubicin Versus Epirubicin**

- Doxorubicin was associated with increased risk of chemical cystitis versus epirubicin (1 trial; RR, 1.85; 95% CI, 1.13 to 3.03), with no clear difference in risk of dysuria or urinary frequency (2 trials) or hematuria (3 trials; RR, 1.53; 95% CI, 0.50 to 4.66;  $I^2 = 0\%$ ) (SOE: low).

### **Doxorubicin Versus Thiotepa**

- One trial found no difference between doxorubicin and thiotepa in risk of bladder irritability (RR, 0.92; 95% CI, 0.36 to 2.37) (SOE: low).

### **Epirubicin Versus Interferon Alpha**

- One trial found no difference between epirubicin and interferon alpha in risk of dysuria or fever (SOE: low).

## **Key Question 8a. Adverse Effects of Treatments: Patient Characteristics**

- No study evaluated how harms of treatment vary in subgroups defined by patient characteristic, such as age, sex, race/ethnicity, performance status, or medical comorbidities (SOE: insufficient).

## **Discussion**

### **Key Findings and Strength of Evidence**

The key findings of this review are described in the summary-of-evidence table (Table A).

**Table A. Summary of the strength of evidence**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
Key Question 1. What is the diagnostic accuracy of various urinary biomarkers compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging) in 1) people with signs or symptoms warranting evaluation for possible bladder cancer or 2) people undergoing surveillance for previously treated bladder cancer?	Quantitative NMP22: sensitivity and specificity	Moderate	Sensitivity was 0.69 (95% CI, 0.62 to 0.75) and specificity 0.77 (95% CI, 0.70 to 0.83), based on 19 studies, for a positive likelihood ratio of 3.05 (95% CI, 2.28 to 4.10) and negative likelihood ratio of 0.40 (95% CI, 0.32 to 0.50).
	Qualitative NMP22: sensitivity and specificity	Low	Sensitivity was 0.58 (95% CI, 0.39 to 0.75) and specificity 0.88 (95% CI, 0.78 to 0.94), based on 4 studies, for a positive likelihood ratio of 4.89 (95% CI, 3.23 to 7.40) and negative likelihood ratio of 0.48 (95% CI, 0.33 to 0.71).
	Qualitative BTA: sensitivity and specificity	Moderate	Sensitivity was 0.64 (95% CI, 0.58 to 0.69; 22 studies) and specificity 0.77 (95% CI, 0.73 to 0.81; 21 studies), for a positive likelihood ratio of 2.80 (95% CI, 2.31 to 3.39) and negative likelihood ratio of 0.47 (95% CI, 0.30 to 0.55).
	Quantitative BTA: sensitivity and specificity	Low	Sensitivity was 0.65 (95% CI, 0.54 to 0.75) and specificity 0.74 (95% CI, 0.64 to 0.82), based on 4 studies, for a positive likelihood ratio of 2.52 (95% CI, 1.86 to 3.41) and negative likelihood ratio of 0.47 (95% CI, 0.37 to 0.61).
	FISH: sensitivity and specificity	Moderate	Sensitivity was 0.63 (95% CI, 0.50 to 0.75) and specificity 0.87 (95% CI, 0.79 to 0.93), based on 11 studies, for a positive likelihood ratio of 5.02 (95% CI, 2.93 to 8.60) and negative likelihood ratio of 0.42 (95% CI, 0.30 to 0.59).
	ImmunoCyt™: sensitivity and specificity	Moderate	Sensitivity was 0.78 (95% CI, 0.68 to 0.85) and specificity 0.78 (95% CI, 0.72 to 0.82), based on 14 studies, for a positive likelihood ratio of 3.49 (95% CI, 2.82 to 4.32) and negative likelihood ratio of 0.29 (95% CI, 0.20 to 0.41).
	CxBladder™: sensitivity and specificity	Low	Sensitivity was 0.82 (95% CI, 0.70 to 0.90) and specificity 0.85 (95% CI, 0.81 to 0.88) for evaluation of symptoms, based on 1 study, for a positive likelihood ratio of 5.53 (95% CI, 4.28 to 7.15) and negative likelihood ratio of 0.21 (95% CI, 0.13 to 0.36).

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Quantitative NMP22 versus qualitative BTA: sensitivity and specificity	Moderate	Based on 7 studies, there was no difference between quantitative NMP22 (cutoff >10 U/mL) and qualitative BTA in sensitivity (0.69; 95% CI, 0.62 to 0.76 vs. 0.66; 95% CI, 0.59 to 0.73, for a difference of 0.03; 95% CI, -0.04 to 0.10) or specificity (0.73; 95% CI, 0.62 to 0.82 vs. 0.76; 95% CI, 0.66 to 0.84, for a difference of 0.03; 95% CI, -0.08 to 0.01).
	ImmunoCyt versus FISH: sensitivity vs. specificity	Low	ImmunoCyt was associated with higher sensitivity than FISH (0.71; 95% CI, 0.54 to 0.84 vs. 0.61; 95% CI, 0.43 to 0.76, for a difference of 0.11; 95% CI, 0.001 to 0.21) but lower specificity (0.71; 95% CI, 0.62 to 0.79 vs. 0.79; 95% CI, 0.71 to 0.85, for a difference of -0.08; 95% CI, -0.15 to -0.001), based on 3 studies.
	Other head-to-head comparisons of urinary biomarkers	Insufficient	Evidence for other head-to-head comparisons of urinary biomarkers was based on small numbers of studies with imprecise estimates and methodological shortcomings, precluding reliable conclusions regarding comparative test performance.
	Various urinary biomarkers plus cytology vs. the urinary biomarker alone: sensitivity and specificity	Moderate	Sixteen studies found various urinary biomarkers plus cytology to be associated with higher sensitivity than the urinary biomarker alone (0.81; 95% CI, 0.75 to 0.86 vs. 0.69; 95% CI, 0.61 to 0.76, for a difference of 0.13; 95% CI, 0.08 to 0.17), with no difference in specificity.
Key Question 1a. Does the diagnostic accuracy differ according to patient characteristics (e.g., age, sex, race/ethnicity), or according to the nature of the presenting signs or symptoms?	Effects of tumor stage: sensitivity	High	Across urinary biomarkers, sensitivity increased with higher tumor stage. Evidence was most robust for quantitative NMP22 (11 studies), qualitative BTA (18 studies), and FISH (8 studies); the association between higher tumor stage and increased sensitivity was least pronounced for ImmunoCyt (10 studies). Sensitivity was generally similar to or slightly lower for CIS tumors than for T1 tumors.

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Effects of tumor grade: sensitivity	High	Across urinary biomarkers, sensitivity increased with higher tumor grade. Evidence was most robust for quantitative NMP22 (12 studies), ImmunoCyt (10 studies), qualitative BTA (18 studies), and FISH (9 studies).
	Effects of tumor size: sensitivity	Low	Two studies found that sensitivity was higher for larger (>1 cm or >2 cm) vs. smaller tumors.
	Effects of patient characteristics (age, sex, smoking status, and presence of other clinical conditions): sensitivity and specificity	Low	Evidence on the effects of patient characteristics, such as age, sex, smoking status, and presence of other clinical conditions, on diagnostic accuracy of urinary biomarkers was limited but did not clearly or consistently indicate effects on sensitivity or specificity.
Key Question 2. For patients with non–muscle-invasive bladder cancer, does the use of a formal risk-adapted assessment approach to treatment decisions (e.g., Guidelines of the European Association of Urology or based on urinary biomarker tests) decrease mortality or improve other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with treatment not guided by a formal assessed risk-adapted approach?	Mortality, recurrence, progression, need for cystectomy, quality of life	Insufficient	No studies.
Key Question 3. For patients with non–muscle-invasive bladder cancer treated with transurethral resection of bladder tumor (TURBT), what is the effectiveness of various intravesical chemotherapeutic or immunotherapeutic agents for decreasing mortality or improving other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with TURBT alone?	<i>BCG vs. no intravesical therapy</i> : All-cause mortality	Insufficient	No trial evaluated effects of BCG vs. no intravesical therapy on risk of all-cause mortality.
	<i>BCG vs. no intravesical therapy</i> : Bladder cancer–specific mortality	Insufficient	One trial found BCG to be associated with decreased risk of bladder cancer–specific mortality vs. no intravesical therapy, but the difference was not statistically significant (RR, 0.62; 95% CI, 0.32 to 1.19).
	<i>BCG vs. no intravesical therapy</i> : Recurrence	Low	BCG was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy (3 trials; RR, 0.56; 95% CI, 0.43 to 0.71; $I^2 = 0\%$ ).
	<i>BCG vs. no intravesical therapy</i> : Progression	Low	BCG was associated with decreased risk of bladder cancer progression (4 trials; RR, 0.39; 95% CI, 0.24 to 0.64; $I^2 = 40\%$ ) vs. no intravesical therapy.

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>MMC vs. no intravesical therapy: All-cause mortality</i>	Low	There was no difference in risk of all cause-mortality for MMC vs. no intravesical therapy (1 trial; HR, 1.17; 95% CI, 0.89 to 1.53).
	<i>MMC vs. no intravesical therapy: Bladder cancer-specific mortality</i>	Low	The effects on bladder cancer-specific mortality were not statistically significant for MMC vs. no intravesical therapy (1 trial; HR, 0.71; 95% CI, 0.34 to 1.46).
	<i>MMC vs. no intravesical therapy: Recurrence</i>	Moderate	MMC was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy (8 trials; RR, 0.71; 95% CI, 0.57 to 0.89; $I^2 = 72\%$ ).
	<i>MMC vs. no intravesical therapy: Progression</i>	Low	Effects of MMC on bladder cancer progression were not statistically significant (5 trials; RR, 0.68; 95% CI, 0.39 to 1.20; $I^2 = 0\%$ ) vs. no intravesical therapy.
	<i>Doxorubicin vs. no intravesical therapy: All-cause mortality</i>	Low	Doxorubicin was associated with no clear effects on all-cause mortality (2 trials) vs. no intravesical therapy.
	<i>Doxorubicin vs. no intravesical therapy: Bladder cancer-specific mortality</i>	Low	Doxorubicin was associated with no clear effects on bladder cancer-specific mortality (1 trial) vs. no intravesical therapy.
	<i>Doxorubicin vs. no intravesical therapy: Recurrence</i>	Moderate	Doxorubicin was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy (10 trials; RR, 0.80; 95% CI, 0.72 to 0.88; $I^2 = 46\%$ ).
	<i>Doxorubicin vs. no intravesical therapy: Progression</i>	Low	Doxorubicin was associated with no difference in risk of bladder cancer progression (5 trials; RR, 1.03; 95% CI, 0.72 to 1.46; $I^2 = 0.0\%$ ) vs. no intravesical therapy.
	<i>Epirubicin vs. no intravesical therapy: Recurrence</i>	Moderate	Epirubicin was associated with decreased risk of bladder cancer recurrence (9 trials; RR, 0.63; 95% CI, 0.53 to 0.75; $I^2 = 64\%$ ) vs. no intravesical therapy.
	<i>Epirubicin vs. no intravesical therapy: Progression</i>	Low	Epirubicin was associated with a non-statistically significant effect on bladder cancer progression (8 trials; RR, 0.79; 95% CI, 0.84 to 1.30; $I^2 = 27\%$ ).
	<i>Gemcitabine vs. no intravesical therapy: All-cause mortality, bladder cancer-specific mortality, progression</i>	Insufficient	Estimates for progression (RR, 3.00; 95% CI, 0.32 to 28.4), all-cause mortality (RR, 0.50; 95% CI, 0.13 to 2.00), and bladder cancer-specific mortality (RR, 1.00; 95% CI, 0.06 to 15.81) were very imprecise for gemcitabine vs. no intravesical therapy.

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>Gemcitabine vs. no intravesical therapy: Recurrence</i>	Low	One trial found no difference between single-instillation gemcitabine vs. no intravesical therapy in risk of bladder cancer recurrence (RR, 0.98; 95% CI, 0.70 to 1.36).
	<i>Interferon alpha vs. no intravesical therapy: Bladder cancer-specific mortality</i>	Low	Interferon alpha was associated with no difference in risk of bladder cancer-specific mortality (1 trial; RR, 1.00; 95% CI, 0.15 to 6.75).
	<i>Interferon alpha vs. no intravesical therapy: Recurrence</i>	Low	Interferon alpha was associated with a non-statistically significant reduction in risk for bladder cancer recurrence vs. no intravesical therapy (3 trials; RR, 0.75; 95% CI, 0.53 to 1.06; $I^2 = 50\%$ ).
	<i>Interferon alpha vs. no intravesical therapy: Progression</i>	Low	Interferon alpha was associated with decreased risk of bladder cancer progression vs. no intravesical therapy (2 trials; RR, 0.33; 95% CI, 0.14 to 0.76; $I^2 = 0\%$ ).
	<i>Interferon gamma vs. no intravesical therapy: Recurrence</i>	Low	Interferon gamma was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy (1 trial; RR, 0.72; 95% CI, 0.51 to 1.01).
	<i>Interferon gamma vs. no intravesical therapy: Progression</i>	Low	Interferon gamma was associated with no difference in risk of bladder cancer progression vs. no intravesical therapy (1 trial; RR, 1.08; 95% CI, 0.07 to 16.4).
	<i>Thiotepa vs. no intravesical therapy: Recurrence</i>	Low	Thiotepa was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy in 5 trials (RR, 0.78; 95% CI, 0.58 to 1.06; $I^2 = 69\%$ ).
Key Question 3a. What is the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents, as monotherapy or in combination?	<i>BCG vs. MMC: All-cause mortality</i>	Moderate	There was no difference in risk of all-cause mortality between BCG and MMC (7 trials; RR, 0.94; 95% CI, 0.83 to 1.06; $I^2 = 0\%$ ).
	<i>BCG vs. MMC: Bladder cancer-specific mortality</i>	Moderate	There was no difference between BCG and MMC in risk of bladder cancer-specific mortality (5 trials; RR, 0.77; 95% CI, 0.54 to 1.10; $I^2 = 0\%$ ).
	<i>BCG vs. MMC: Recurrence</i>	Low	There were no differences between BCG and MMC in risk of bladder cancer recurrence (10 trials; RR, 0.95; 95% CI, 0.81 to 1.11; $I^2 = 67\%$ ).
	<i>BCG vs. MMC: Progression</i>	Moderate	There was no difference in risk of progression (7 trials; RR, 0.88; 95% CI, 0.66 to 1.17; $I^2 = 18\%$ ).

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG alone vs. BCG plus MMC given sequentially:</i> All-cause mortality, bladder cancer-specific mortality, recurrence, progression	Low	There were no differences sequentially in risk of all-cause (1 trial; RR, 1.57; 95% CI, 0.67 to 3.71) or bladder cancer-specific mortality (2 trials; RR, 1.10; 95% CI, 0.50 to 2.38; $I^2 = 17\%$ ), bladder cancer recurrence (4 trials; RR, 1.03; 95% CI, 0.70 to 1.52; $I^2 = 75\%$ ), progression (3 trials; RR, 0.87; 95% CI, 0.40 to 1.91; $I^2 = 22\%$ ), or cystectomy (4 trials; RR, 0.87; 95% CI, 0.41 to 1.84; $I^2 = 0\%$ ).
	<i>BCG plus MMC given sequentially vs. MMC alone:</i> All-cause mortality, bladder cancer-specific mortality, recurrence, progression	Low	There were no differences in risk of all-cause (2 trials; RR, 1.53; 95% CI, 0.72 to 1.74 and RR, 0.95; 95% CI, 0.71 to 1.30) or bladder cancer-specific mortality (2 trials; RR, 0.64; 95% CI, 0.22 to 1.88 and RR, 0.95; 95% CI, 0.45 to 1.56), bladder cancer recurrence (2 trials; RR, 0.88; 95% CI, 0.75 to 1.03; $I^2 = 0\%$ ), or progression (2 trials; RR, 0.82; 95% CI, 0.40 to 1.68 and RR, 1.28; 95% CI, 0.35 to 4.61).
	<i>BCG vs. doxorubicin:</i> All-cause mortality, recurrence, progression	Low	BCG was associated with decreased risk of bladder cancer recurrence vs. doxorubicin (2 trials; RR, 0.31; 95% CI, 0.16 to 0.61 and RR, 0.75; 95% CI, 0.64 to 0.88), but there was no difference in risk of all-cause mortality (2 trials; RR, 0.40; 95% CI, 0.01 to 12 and RR, 1.00; 95% CI, 0.71 to 1.37) or bladder cancer progression (1 trial; RR, 0.20; 95% CI, 0.02 to 1.72).
	<i>BCG vs. epirubicin:</i> All-cause mortality	Low	Estimates favored BCG for all-cause mortality, but differences were not statistically significant (3 trials; RR, 0.72; 95% CI, 0.44 to 1.19; $I^2 = 87\%$ ).
	<i>BCG vs. epirubicin:</i> Bladder cancer-specific mortality	Low	Estimates favored BCG for bladder cancer-specific mortality, but differences were not statistically significant (3 trials; RR, 0.72; 95% CI, 0.25 to 2.08; $I^2 = 80\%$ ).
	<i>BCG vs. epirubicin:</i> Recurrence	Moderate	BCG was associated with reduced risk of bladder cancer recurrence, but statistical heterogeneity was high (5 trials; RR, 0.54; 95% CI, 0.40 to 0.74; $I^2 = 76\%$ ).

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG vs. epirubicin:</i> Progression	Low	Estimates favored BCG for bladder cancer progression, but differences were not statistically significant (5 trials; RR, 0.60; 95% CI, 0.36 to 1.01; $I^2 = 47\%$ ).
	<i>BCG alone vs. BCG plus epirubicin given sequentially:</i> Recurrence, progression	Low	There were no differences in risk of bladder cancer recurrence (3 trials; RR, 1.25; 95% CI, 0.92 to 1.69; $I^2 = 0\%$ ). BCG was associated with increased risk of bladder cancer progression, but the difference was not statistically significant (3 trials; RR, 1.92; 95% CI, 0.73 to 5.07; $I^2 = 0\%$ ).
	<i>BCG vs. epirubicin plus interferon:</i> Bladder cancer-specific mortality, progression	Low	One trial found no differences in risk of bladder cancer-specific mortality (RR, 0.79; 95% CI, 0.32 to 1.63) or progression-free survival, although BCG was associated with decreased risk of bladder cancer recurrence (RR, 0.66; 95% CI, 0.51 to 0.85).
	<i>BCG vs. gemcitabine:</i> All-cause mortality	Low	There were no differences in risk of all-cause mortality (1 trial; RR, 1.20; 95% CI, 0.04 to 34).
	<i>BCG vs. gemcitabine:</i> Recurrence	Insufficient	Evidence from 3 trials was insufficient to determine risk of bladder cancer recurrence because of clinical heterogeneity and inconsistent findings (RR, 1.67; 95% CI, 1.21 to 2.29; RR, 0.53; 95% CI, 0.28 to 1.01; and RR, 0.76; 95% CI, 0.44 to 1.90).
	<i>BCG vs. gemcitabine:</i> Progression	Low	There were no differences in risk of progression (2 trials; RR, 1.11; 95% CI, 0.53 to 2.34 and RR, 0.52; 95% CI, 0.13 to 2.06).
	<i>BCG vs. gemcitabine:</i> Quality of life	Low	There were no differences for BCG vs. gemcitabine in quality of life (1 trial).
	<i>BCG alone vs. BCG plus gemcitabine given sequentially:</i> Recurrence, progression	Low	There were no differences in risk of bladder cancer recurrence (1 trial; RR, 0.86; 95% CI, 0.49 to 1.51) or progression (1 trial; RR, 1.18; 95% CI, 0.30 to 4.61).
	<i>BCG vs. interferon alpha-2a:</i> Recurrence, progression	Low	BCG was associated with reduced risk of bladder cancer recurrence (1 trial; RR, 0.57; 95% CI, 0.39 to 0.82), but the difference in risk of bladder cancer progression was not statistically significant (1 trial; RR, 0.69; 95% CI, 0.25 to 1.92).

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG alone vs. alternating BCG and interferon alpha-2b:</i> Recurrence	Low	BCG alone was associated with reduced risk of bladder cancer recurrence (1 trial; RR, 0.42; 95% CI, 0.30 to 0.59).
	<i>BCG alone vs. coadministration of BCG and interferon alpha-2b:</i> Recurrence, progression	Low	Differences in risk of bladder cancer recurrence (1 trial; RR, 0.88; 95% CI, 0.71 to 1.08) or progression (1 trial; RR, 0.76; 95% CI, 0.17 to 3.30) did not reach statistical significance.
	<i>BCG vs. thiotepa:</i> Recurrence	Low	Two trials found maintenance therapy with BCG to be associated with decreased risk of recurrence vs. thiotepa (RR, 0.38; 95% CI, 0.19 to 0.76 and RR, 0.04; 95% CI, 0.00 to 0.63).
	<i>BCG vs. thiotepa:</i> Progression, mortality, and cystectomy	Insufficient	Estimates were too imprecise to evaluate effects.
	<i>MMC vs. doxorubicin:</i> Recurrence, progression	Low	There was no difference in risk of bladder cancer recurrence (6 trials; RR, 1.00; 95% CI, 0.82 to 1.22; $I^2 = 44\%$ ), but MMC was associated with a non-statistically significant trend toward decreased risk of bladder cancer progression (4 trials; RR, 0.63; 95% CI, 0.37 to 1.08; $I^2 = 21\%$ ).
	<i>MMC vs. epirubicin:</i> Recurrence	Low	There was no difference in risk of bladder cancer recurrence in 1 trial (RR, 1.16; 95% CI, 0.52 to 2.58).
	<i>MMC vs. gemcitabine:</i> Recurrence, progression	Low	In 1 trial, there was no difference in risk of bladder cancer progression ( $p = 0.29$ ). MMC was associated with increased risk of recurrence, but the difference was not statistically significant (RR, 1.64; 95% CI, 0.64 to 4.19).
	<i>MMC vs. interferon alpha:</i> Recurrence, progression	Low	One trial found no difference between MMC and interferon alpha in risk of bladder cancer recurrence (RR, 0.77; 95% CI, 0.58 to 1.01) or bladder cancer progression (RR, 1.38; 95% CI, 0.49 to 3.88).
	<i>MMC vs. interferon gamma:</i> Recurrence	Low	MMC was associated with increased risk of bladder cancer recurrence in 1 trial (RR, 1.61; 95% CI, 0.97 to 2.67).
	<i>MMC vs. thiotepa:</i> Recurrence	Low	Two trials found no difference between MMC and thiotepa in risk of recurrence (RR, 1.76; 95% CI, 0.36 to 8.70 and RR, 1.14; 95% CI, 0.60 to 2.16).

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>Doxorubicin vs. epirubicin:</i> Recurrence, progression	Low	Doxorubicin was associated with increased risk of bladder cancer recurrence (3 trials; RR, 1.56; 95% CI, 1.08 to 2.22; $I^2 = 0\%$ ); the difference in risk of progression was not statistically significant (1 trial; RR, 1.32; 95% CI, 0.50 to 3.47).
	<i>Doxorubicin vs. thiotepa:</i> Recurrence	Low	There was no statistically significant difference in risk of bladder cancer recurrence (RR, 1.22; 95% CI, 0.76 to 1.94).
	<i>Doxorubicin vs. thiotepa:</i> Progression, noncancer mortality, cancer-specific mortality	Insufficient	Estimates from 1 trial for progression (RR, 2.11; 95% CI, 0.40 to 11.06), noncancer mortality (RR, 0.35; 95% CI, 0.01 to 8.45), and cancer-specific mortality (RR, 3.17; 95% CI, 0.13 to 76.1) were very imprecise.
	<i>Epirubicin vs. interferon alpha:</i> Recurrence	Low	Epirubicin was associated with decreased risk of bladder cancer recurrence in 1 trial (RR, 0.67; 95% CI, 0.49 to 0.91).
Key Question 3b. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers?	Stage, grade, tumor multiplicity, primary vs. recurrent	Low	There were no clear differences in estimates of effectiveness of intravesical therapies in subgroups defined by tumor stage, grade, size, multiplicity, recurrence status, or DNA ploidy.
Key Question 3c. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities?	Age, sex, race/ethnicity, performance status, comorbidities	Insufficient	No studies.
	Recurrence, disease-free survival	Low	In patients with recurrence or progression following prior BCG therapy, 1 trial found maintenance therapy with gemcitabine to be associated with decreased risk of recurrence vs. repeat treatment with BCG, and 1 trial found MMC maintenance therapy to be associated with lower likelihood of disease-free survival than gemcitabine; estimates for progression were imprecise.
Key Question 3d. Does the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents differ according to dosing frequency, duration of treatment, and/or the timing of administration relative to TURBT?	Standard vs. lower dose BCG: recurrence, progression, mortality, adverse events	Low	Six trials found no clear differences in risk of recurrence, progression, or bladder cancer mortality, including in patients with higher risk NMIBC, although there was some inconsistency between trials. Standard therapy was associated with increased risk of local and systemic adverse events vs. lower dose BCG.

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Maintenance vs. induction BCG: recurrence, progression, adverse events	Low	Two trials found more prolonged courses of BCG to be associated with decreased risk of bladder cancer recurrence vs. induction therapy in patients with higher risk NMIBC (RR, 0.54; 95% CI, 0.31 to 0.95) but increased risk of adverse events.
	BCG maintenance for 1 vs. 3 years: recurrence, progression, mortality, adverse events	Low	One trial of patients with solitary T1/G3 or multiple Ta–T1/G1–G3 tumors found no difference between 1 vs. 3 years of BCG maintenance therapy in risk of recurrence, progression, mortality, or adverse events.
	MMC single vs. 5 instillations: recurrence, progression, mortality, adverse events	Low	One trial of patients with NMIBC (not selected for being at higher risk) found no clear differences in risk of recurrence, progression, or mortality. The single instillation was associated with lower risk of local adverse events.
	MMC induction vs. maintenance: recurrence, adverse events	Low	One trial of patients with higher risk NMIBC found MMC 20 mg induction therapy for 6 weeks to be associated with higher risk of recurrence than maintenance therapy. There were no clear differences in risk of adverse events.
	MMC maintenance therapy with increased frequency and number of instillations vs. fewer instillations: recurrence, progression, adverse events	Low	Two trials of MMC maintenance regimens in patients with NMIBC not selected for being at higher risk found some evidence that a higher total number of instillations and increased frequency during initial therapy were associated with lower risk of recurrence and progression, and might be associated with lower risk of local adverse events.
	MMC optimized through alkalization of urine vs. nonoptimized administration: recurrence, adverse events	Low	One trial found no difference between “optimized” versus nonoptimized administration of intravesical MMC in risk of recurrence in patients with low-risk NMIBC, but 1 other trial of patients with higher risk NMIBC found optimized administration to be associated with lower risk of recurrence and increased risk of local adverse events.

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Doxorubicin 8 weeks vs. 2 years: recurrence, progression, adverse events	Low	Two trials of patients with NMIBC not selected for being at higher risk found no differences between doxorubicin 30 mg and 20 mg given as short (8 weeks) or long (2 years) regimens in risk of recurrence or progression, with no differences in adverse events.
	Doxorubicin induction vs. maintenance: recurrence, progression, mortality, adverse events	Low	Two trials of patients with NMIBC not selected for being at higher risk found no clear differences between doxorubicin induction therapy and induction plus maintenance in risk of recurrence, progression, or mortality, with no differences in adverse events.
	Doxorubicin prior to vs. after TURBT: recurrence, adverse events	Low	Two trials of doxorubicin found no clear benefits associated with administration prior to TURBT or multiple instillations immediately after TURBT, with some evidence of increased adverse events with multiple immediate post-TURBT instillations.
	Epirubicin higher vs. lower doses: recurrence, progression, adverse events	Moderate	Three trials of epirubicin found no clear evidence that higher doses are associated with reduced risk of recurrence or progression vs. lower doses, with no differences in adverse events.
	Epirubicin single vs. multiple instillations: recurrence, progression, bladder cancer mortality, adverse events	Moderate	Three trials found no clear difference between single-instillation epirubicin and multiple instillations in patients with low- or high-risk NMIBC in risk of recurrence, progression, or bladder cancer mortality, with some evidence of lower risk of local adverse events with single instillation.
	Epirubicin maintenance vs. induction without maintenance: recurrence, progression, adverse events	Moderate	Two trials found no clear differences between epirubicin maintenance therapy and induction without maintenance in risk of recurrence or progression, including 1 trial of patients with higher risk NMIBC. There were no differences in risk of local adverse events.

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Epirubicin, more vs. less intensive therapy: recurrence, adverse events	Low	Five trials that evaluated different epirubicin regimens that included maintenance therapy found some evidence that more intensive therapy is associated with decreased risk of recurrence, but results were inconsistent. There was no difference in risk of adverse events.
	Thiotepa 30 vs. 60 mg: recurrence, adverse events	Low	Two trials found no clear differences between thiotepa 30 mg and 60 mg for maintenance or for treatment of incompletely resected NMIBC or CIS.
	Interferon alpha-2b, high vs. lower doses: recurrence, progression, resolution of bladder cancer marker lesions	Low	Three trials found higher doses of interferon alpha-2b to be associated with improved outcomes related to recurrence, progression, or resolution of bladder cancer marker lesions vs. lower doses, but most estimates were imprecise and did not reach statistical significance. There were no clear differences in risk of local or systemic adverse events.
	MMC or doxorubicin on day of TURBT vs. 1 to 2 weeks after TURBT: recurrence, progression, mortality, adverse events	Low	One trial found no difference between initiation of intravesical therapy (9 instillations over 6 months) with MMC or doxorubicin 50 mg on the day of TURBT versus 1 to 2 weeks after TURBT in risk of recurrence, progression, or mortality.
	MMC or doxorubicin maintenance vs. no maintenance: recurrence, progression, mortality, adverse events	Low	One trial found no difference between maintenance beyond 6 months vs. no additional maintenance therapy. There were no clear differences in local or systemic adverse events.
Key Question 4. For patients with high risk non--muscle-invasive bladder cancer treated with TURBT, what is the effectiveness of external beam radiation therapy (either alone or with systemic chemotherapy/immunotherapy) for decreasing mortality or improving other outcomes compared with intravesical chemotherapy/immunotherapy alone or cystectomy?	Mortality, recurrence, progression	Low	One randomized trial of patients with T1G3 bladder cancer found no effects of radiation therapy vs. no radiotherapy (for unifocal disease and no CIS) or radiation therapy vs. intravesical therapy (for multifocal disease or CIS) in recurrence-free survival (HR, 0.94; 95% CI, 0.67 to 1.30), progression-free interval (HR, 1.07; 95% CI, 0.65 to 1.74), progression-free survival (HR, 1.35; 95% CI, 0.92 to 1.98), or overall survival (HR, 1.32; 95% CI, 0.86 to 2.04) after 5 years.

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
Key Question 5. In surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of various urinary biomarkers to decrease mortality or improve other outcomes compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging)?	Mortality	Insufficient	No studies.
Key Question 5a. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers?		Insufficient	No studies.
Key Question 5b. Does the comparative effectiveness differ according to the treatment used (i.e., specific chemotherapeutic or immunotherapeutic agents and/or TURBT)?		Insufficient	No studies.
Key Question 5c. Does the comparative effectiveness differ according to the length of surveillance intervals?		Insufficient	No studies.
Key Question 5d. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, or race/ethnicity?		Insufficient	No studies.
Key Question 6. For initial diagnosis or surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of blue light or other methods of augmented cystoscopy compared with standard cystoscopy for recurrence rates, progression of bladder cancer, mortality, or other clinical outcomes?	<i>Fluorescent cystoscopy vs. white light cystoscopy: Mortality</i>	Low	There was no difference between fluorescent and white light cystoscopy in risk of mortality (3 trials; RR, 1.28; 95% CI, 0.55 to 2.95; $I^2 = 41\%$ ).

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>Fluorescent cystoscopy vs. white light cystoscopy:</i> Recurrence	Low	Fluorescent cystoscopy with 5-ALA or HAL was associated with decreased risk of bladder cancer recurrence vs. white light cystoscopy at short-term (<3 months; 9 trials; RR, 0.58; 95% CI, 0.36 to 0.94; $I^2=75\%$ ), intermediate-term (3 months to <1 year; 5 trials; RR, 0.67; 95% CI, 0.51 to 0.88; $I^2=35\%$ ), and long-term followup ( $\geq 1$ year; 11 trials; RR, 0.81; 95% CI, 0.68 to 0.98; $I^2=64\%$ ), but findings were inconsistent and potentially susceptible to performance bias (because of failure to blind the initial cystoscopy) and publication bias.
	<i>Fluorescent cystoscopy vs. white light cystoscopy:</i> Progression	Moderate	There was no difference between fluorescent and white light cystoscopy in risk of progression to muscle-invasive bladder cancer (9 trials; RR, 0.78; 95% CI, 0.55 to 1.12; $I^2 = 0\%$ ).
	<i>Narrow band imaging vs. white light cystoscopy:</i> Recurrence	Low	Narrow band imaging was associated with lower risk of bladder cancer recurrence at 3 months (3.9% vs. 17%; OR, 0.62; 95% CI, 0.41 to 0.92) and at 12 months (OR, 0.24; 95% CI, 0.07 to 0.81) in 1 trial.
Key Question 7. What are the comparative adverse effects of various tests for diagnosis and post-treatment surveillance of bladder cancer, including urinary biomarkers, cytology, and cystoscopy?	Urinary biomarkers: adverse clinical outcomes	Insufficient	Urinary biomarkers miss 23% to 42% of patients with bladder cancer and are incorrectly positive in 11% to 28% of patients without bladder cancer, but no study directly measured effects of inaccurate diagnosis on clinical outcomes.
	Fluorescent vs. white light cystoscopy: false-positives	Low	There were no clear differences between fluorescent cystoscopy and white light cystoscopy in risk of false-positives in 2 trials.
	Fluorescent vs. white light cystoscopy: renal and genitourinary adverse events	Low	There were no clear differences between fluorescent cystoscopy and white light cystoscopy in risk of renal and genitourinary adverse events in 2 trials.

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
Key Question 8. What are the comparative adverse effects of various treatments for non--muscle-invasive bladder cancer, including intravesical chemotherapeutic or immunotherapeutic agents and TURBT?	BCG vs. no intravesical therapy: local and systemic adverse events	Low	Four trials reported granulomatous cystitis or irritative symptoms in 27% to 84% of patients, macroscopic hematuria in 21% to 72%, and fever in 27% to 44%. Harms were not reported in patients who did not receive intravesical therapy.
	Non-BCG intravesical therapies vs. no intravesical therapy: local and systemic adverse events	Low (local adverse events); insufficient (systemic adverse events)	Evidence on harms was very limited, although some trials reported an increased risk of local adverse events. Evidence was insufficient to determine effects of non-BCG intravesical therapies vs. no intravesical therapy on risk of systemic adverse events.
	<i>BCG</i> vs. <i>MMC</i> : Local adverse events	Low (moderate for cystitis and hematuria)	BCG was associated with increased risk of any local adverse event (2 trials; RR, 2.01; 95% CI, 1.59 to 2.54; $I^2 = 0\%$ ), granulomatous cystitis (5 trials; RR, 1.71; 95% CI, 1.22 to 2.41; $I^2 = 58\%$ ), dysuria (3 trials; 48% vs. 32%; RR, 1.23; 95% CI, 1.03 to 1.46; $I^2 = 34\%$ ), and hematuria (6 trials; RR, 1.78; 95% CI, 1.24 to 2.56; $I^2 = 62\%$ ) vs. MMC.
	<i>BCG</i> vs. <i>MMC</i> : Systemic adverse events	Low	BCG was associated with increased risk of any systemic adverse event (2 trials; RR, 2.01; 95% CI, 1.59 to 2.54; $I^2 = 0\%$ ) and fever (4 trials; RR, 4.51; 95% CI, 2.31 to 8.82; $I^2 = 25\%$ ) vs. MMC.
	<i>BCG</i> alone vs. <i>BCG</i> plus <i>MMC</i> given sequentially: Discontinuation of therapy	Low	BCG alone was associated with increased risk of discontinuation of instillations vs. BCG plus MMC given sequentially (1 trial; RR, 4.06; 95% CI, 2.09 to 7.86).
	<i>BCG</i> plus <i>MMC</i> given sequentially vs. <i>MMC</i> alone: Local adverse events	Low	There was no difference between sequentially administered BCG plus MMC and MMC alone in local adverse events (1 trial; RR, 1.36; 95% CI, 0.60 to 3.08) or risk of granulomatous cystitis (1 trial; RR, 1.30; 95% CI, 0.88 to 1.93).
	<i>BCG</i> plus <i>MMC</i> given sequentially vs. <i>MMC</i> alone: Systemic adverse events	Low	There was no difference between BCG and MMC given sequentially and MMC used alone in systemic adverse events (1 trial; RR, 1.07; 95% CI, 0.63 to 1.84), but BCG plus MMC was associated with increased risk of fever (1 trial; 12% vs. 3%; RR, 3.75; 95% CI, 1.08 to 13).

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG plus MMC given sequentially vs. MMC alone:</i> Discontinuation of therapy	Low	There was no difference between alternating BCG plus MMC and MMC alone in risk of discontinuation of instillations in patients with CIS (1 trial; RR, 0.54; 95% CI, 0.16 to 1.84) or in patients with Ta or T1 tumors (1 trial; RR, 0.93; 95% CI, 0.52 to 1.65).
	<i>BCG vs. doxorubicin:</i> Local adverse events	Low (cystitis); insufficient (dysuria and hematuria)	BCG was associated with increased risk of cystitis vs. doxorubicin (1 trial; RR, 17; 95% CI, 1 to 289), but there was insufficient evidence to determine effects on dysuria (3 trials; data not pooled) and hematuria (2 trials; data not pooled) because of small numbers of trials with inconsistent results.
	<i>BCG vs. epirubicin:</i> Local adverse events	Low	BCG was associated with increased risk of local side effects (1 trial; RR, 3.28; 95% CI, 1.26 to 8.53).
	<i>BCG vs. epirubicin:</i> Discontinuation of therapy	Insufficient	Results were mixed for discontinuation of intravesical therapy (2 trials; data not pooled).
	<i>BCG vs. epirubicin:</i> Systemic adverse events	Low	BCG was associated with increased risk of granulomatous cystitis (4 trials; RR, 1.86; 95% CI, 1.35 to 2.56; $I^2 = 65\%$ ), dysuria (1 trial; RR, 2.43; 95% CI, 1.13 to 5.24), hematuria (4 trials; RR, 1.77; 95% CI, 1.41 to 2.22; $I^2 = 0\%$ ), and fever (2 trials; RR, 9.73; 95% CI, 2.72 to 35; $I^2 = 0\%$ ).
	<i>BCG alone vs. BCG plus epirubicin given sequentially:</i> Local adverse events	Low	There was no difference in risk of dysuria (1 trial; RR, 1.22; 95% CI, 0.56 to 2.66) or hematuria (2 trials; RR, 2.27; 95% CI, 0.86 to 6.00; $I^2 = 0\%$ ).
	<i>BCG alone vs. BCG plus epirubicin given sequentially:</i> Systemic adverse events	Low	BCG was associated with increased risk of systemic adverse events (1 trial; RR, 5.97; 95% CI, 2.18 to 16) and granulomatous cystitis (1 trial; RR, 2.28; 95% CI, 1.46 to 3.54) but no difference in risk of fever (2 trials; RR, 2.09; 95% CI, 0.48 to 9.02; $I^2 = 0\%$ ).
	<i>BCG alone vs. BCG plus epirubicin given sequentially:</i> Discontinuation of therapy	Low	BCG was associated with increased risk of discontinuation of instillations (1 trial; RR, 4.56; 95% CI, 1.35 to 15).

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG vs. gemcitabine</i> : Local adverse events	Low	There were no differences between BCG and gemcitabine in risk of local adverse events requiring postponement or discontinuation of intravesical therapy (1 trial; RR, 1.33; 95% CI, 0.32 to 5.49).
	<i>BCG vs. gemcitabine</i> : Systemic adverse events	Low	There were no differences in systemic adverse events (1 trial; RR, 0.50; 95% CI, 0.10 to 2.5), dysuria (2 trials; RR, 1.51; 95% CI, 0.92 to 2.50; $I^2 = 0\%$ ), or hematuria (2 trials; RR, 4.62; 95% CI, 0.78 to 27; $I^2 = 29\%$ ), but BCG was associated with increased risk of fever (2 trials; RR, 6.24; 95% CI, 1.03 to 38; $I^2 = 5\%$ ).
	<i>BCG alone vs. BCG plus gemcitabine given sequentially</i> : Local adverse events	Low	One trial found no difference in risk of dysuria (RR, 0.92; 95% CI, 0.52 to 1.65) or hematuria (RR, 0.30; 95% CI, 0.08 to 1.09).
	<i>BCG vs. interferon alpha-2a</i> : Local adverse events	Low	BCG was associated with increased risk of dysuria (1 trial; RR, 84; 95% CI, 5.29 to 1,319).
	<i>BCG vs. interferon alpha-2a</i> : Systemic adverse events	Low	There was no difference in risk of fever (1 trial; RR, 4.82; 95% CI, 0.25 to 94).
	<i>BCG alone vs. coadministration of BCG and interferon alpha-2b</i> : Systemic adverse events	Low	BCG was associated with increased risk of constitutional symptoms (1 trial; RR, 1.63; 95% CI, 1.12 to 2.38) and fever (1 trial; RR, 2.26; 95% CI, 1.30 to 3.95).
	<i>BCG vs. thiotepa</i> : Local adverse events	Low	BCG was associated with increased risk of bladder irritability (1 trial; RR, 2.93; 95% CI, 1.45 to 5.90) and cystitis (1 trial; RR, 18; 95% CI, 1.11 to 306).
	<i>BCG vs. thiotepa</i> : Systemic adverse events	Low	BCG was associated with increased risk of fever (1 trial; RR, 8.36; 95% CI, 0.47 to 150).
	<i>MMC vs. doxorubicin</i> : Local adverse events	Insufficient	Evidence was insufficient to determine effects of MMC vs. doxorubicin on risk of local adverse events, based on inconsistent results from 6 trials.
	<i>MMC vs. epirubicin</i> : Local adverse events	Low	One small trial found no difference between MMC and epirubicin 80 mg in risk of urinary symptoms.
	<i>MMC vs. interferon alpha</i> : Local adverse events	Low	One trial found MMC to be associated with greater risk of hematuria vs. interferon alpha (RR, 2.00; 95% CI, 1.09 to 3.65) and no difference in risk of dysuria or urinary frequency.

**Table A. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>MMC vs. interferon alpha:</i> Systemic adverse events	Low	One trial found MMC to be associated with decreased risk of fever (RR, 0.13; 95% CI, 0.03 to 0.55).
	<i>MMC vs. gemcitabine:</i> Local adverse events	Low	One trial found MMC to be associated with increased risk of chemical cystitis (RR, 3.93; 95% CI, 1.17 to 13.14), with no difference in risk of dysuria or hematuria.
	<i>Doxorubicin vs. epirubicin:</i> Local adverse events	Low	Doxorubicin was associated with increased risk of chemical cystitis (1 trial; RR, 1.85; 95% CI, 1.13 to 3.03), with no clear difference in risk of dysuria or urinary frequency (2 trials) or hematuria (3 trials; RR, 1.53; 95% CI, 0.50 to 4.66; $I^2 = 0\%$ ).
	<i>Doxorubicin vs. thiotepa:</i> Local adverse events	Low	One trial found no difference in risk of bladder irritability (RR, 0.92; 95% CI, 0.36 to 2.37).
	<i>Epirubicin vs. interferon alpha:</i> Local adverse events	Low	One trial found no difference in risk of dysuria.
	<i>Epirubicin vs. interferon alpha:</i> Systemic adverse events	Low	One trial found no difference in risk of fever.
Key Question 8a. How do adverse effects of treatment vary by patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities such as chronic kidney disease?	Adverse effects	Insufficient	No studies

5-ALA = 5-aminolevulinic acid; BCG = bacillus Calmette-Guérin; BTA = bladder tumor antigen; CI = confidence interval; CIS = carcinoma in situ; FISH = fluorescence in situ hybridization; G = grade; HAL = hexaminolevulinate; HR = hazard ratio; MMC = mitomycin C; NMIBC = non-muscle-invasive bladder cancer; NMP22 = nuclear matrix protein 22; OR = odds ratio; RR = relative risk; T = tumor; TURBT = transurethral resection of bladder tumor

Urinary biomarkers were associated with sensitivity for bladder cancer that ranged from 0.58 to 0.77 and specificity that ranged from 0.72 to 0.89, for positive likelihood ratios that ranged from 2.18 to 6.10 and negative likelihood ratios that ranged from 0.21 to 0.48. Findings were robust in sensitivity and stratified analyses, although evidence was strongest for quantitative NMP22 and qualitative BTA (SOE: moderate) and relatively sparse for other biomarkers (SOE: low). Across urinary biomarkers, sensitivity was greater for higher stage and higher grade tumors (SOE: high). For qualitative BTA, sensitivity was somewhat higher for evaluation of patients with signs or symptoms of bladder cancer than for surveillance of patients previously treated for bladder cancer, but for quantitative NMP22 there was no clear difference in diagnostic accuracy based on reason for testing. Studies that directly compared the accuracy of quantitative NMP22 and qualitative BTA found no differences in diagnostic accuracy (SOE: moderate). There were too few head-to-head comparisons of other urinary biomarkers to reach firm conclusions regarding comparative accuracy. Sensitivity was increased when urinary biomarkers were used

in conjunction with urine cytology (SOE: moderate). No study evaluated clinical outcomes associated with use of urinary biomarkers for diagnosis or surveillance of bladder cancer (SOE: insufficient). Urinary biomarkers miss 23 to 42 percent of patients with bladder cancer and are incorrectly positive in 11 to 28 percent of patients without bladder cancer, which could result in delayed diagnosis or unnecessary cystoscopies and other diagnostic procedures, but no study directly measured effects of inaccurate diagnosis on clinical outcomes (SOE: insufficient).

Most trials found that fluorescent cystoscopy was associated with decreased risk of subsequent bladder recurrence versus white light cystoscopy, but there was no difference in risk of progression or mortality, although data for these outcomes were relatively sparse (SOE: low). In addition, evidence on effects on risk of recurrence was inconsistent, and the only trial<sup>25</sup> designed to minimize performance bias (by blinding the cystoscopist to instillation of photosensitizer vs. placebo) found no difference in risk of bladder cancer recurrence.

Intravesical therapy was effective for reducing risk of bladder cancer recurrence versus no intravesical therapy. Compared with no intravesical therapy, BCG was associated with decreased risk of bladder cancer recurrence (RR, 0.63; 95% CI, 0.50 to 0.79) as well as progression (RR, 0.50; 95% CI, 0.32 to 0.77) (SOE: moderate). MMC, doxorubicin, and epirubicin were also associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (RR, 0.66 to 0.80), but effects on bladder cancer progression were not statistically significant (MMC and epirubicin) or showed no effect (doxorubicin). Although trials varied with respect to doses, instillation regimens, and patient populations evaluated, findings were generally robust in sensitivity and subgroup analyses. No intravesical agent, including BCG, was associated with decreased risk of all-cause or bladder cancer–specific mortality versus no intravesical therapy. Evidence on gemcitabine, interferon alpha, and thiotepa was sparse, and we found no randomized trials of valrubicin, paclitaxel, or apaziquone.

Head-to-head trials of intravesical therapy using different drugs showed few clear differences. For BCG versus MMC, the most well-studied comparison, there was no difference on any outcome, including bladder cancer recurrence, progression, or mortality (SOE: moderate). However, BCG was associated with decreased risk of bladder cancer recurrence in the subgroup of trials that evaluated maintenance regimens (SOE: low). Other head-to-head comparisons were evaluated in fewer trials, and in general showed few differences. A possible exception was for BCG versus epirubicin, for which there was some evidence that BCG might be associated with decreased risk of bladder cancer recurrence and progression versus epirubicin (SOE: low). Although doxorubicin was associated with increased risk of bladder cancer recurrence versus epirubicin (RR, 1.56; 95% CI, 1.08 to 2.22), this finding was based on only three trials (SOE: low).<sup>26-28</sup> Evidence to determine the effects of tumor characteristics on estimates of effectiveness of intravesical therapies was limited but indicated no differences in risk estimates based on factors such as tumor stage, grade, multiplicity, recurrence status, and size (SOE: low). However, even if relative estimates of effectiveness are similar, absolute effects will vary depending on the underlying incidence of recurrence, progression, mortality, or other outcomes. Therefore, patients with higher stage, higher grade, multiple, recurrent, or larger tumors would be expected to experience greater absolute benefits. Evidence to determine the effects of patient characteristics, such as age, sex, race/ethnicity, performance status, or comorbidities, on estimates of effectiveness of intravesical therapies was not available.

Results from trials that compared effects of intravesical therapy using different doses or instillation regimens for the same agent were difficult to interpret because of variability in the patient populations, doses, instillation regimens, and other factors. For BCG, there were no clear

differences between standard and lower doses in risk of bladder cancer recurrence, progression, or mortality, including in patients with higher risk NMIBC, but there was some inconsistency between trials (SOE: low). Limited evidence suggested that BCG maintenance regimens (>6 weeks) are more effective than induction regimens (≤6 weeks) at reducing risk of bladder cancer recurrence in patients with higher risk tumors (SOE: low). Trials on the effects of dose and duration of other intravesical agents on outcomes reported inconsistent results and were clinically heterogeneous, making it difficult to draw strong conclusions (SOE: insufficient to low). However, there is no evidence that prolonging therapy for more than 1 year is more effective than shorter regimens.

Evidence on harms associated with intravesical therapies was more limited than evidence on benefits. Trials of BCG versus no intravesical therapy found that local and systemic adverse events were relatively common (chemical cystitis or irritative symptoms in 27% to 84% of patients, macroscopic hematuria in 21% to 72%, and fever in 27% to 44%) (SOE: low). BCG was also associated with an increased risk of local adverse events and fever versus MMC (SOE: low to moderate). Standard-dose BCG was associated with increased risk of local and systemic adverse events versus lower dose BCG. Few trials reported harms of intravesical agents other than BCG versus no intravesical therapy or versus another intravesical agent.

The only randomized trial of radiation therapy found no effects on recurrence, progression, or survival in patients with T1 Grade (G) 3 cancers when compared with no radiotherapy (for unifocal cancers and no CIS) or against intravesical therapy (for multifocal disease or CIS) (SOE: low).<sup>29</sup>

## **Findings in Relationship to What Is Already Known**

Our findings on diagnostic accuracy were generally consistent with prior systematic reviews that found urinary biomarkers insufficiently accurate to replace cystoscopy.<sup>30-32</sup> Estimates for sensitivity and specificity were generally similar in our review and prior reviews, even though we excluded case-control studies and included more recently published studies. In addition, prior reviews did not evaluate potential differences in diagnostic accuracy for testing performed for evaluation of signs and symptoms of bladder cancer versus for surveillance.

Prior systematic reviews<sup>33,34</sup> found fluorescent cystoscopy to be associated with decreased risk of recurrent bladder cancer versus white light cystoscopy, but they were published prior to a recent trial that was the only one to blind the cystoscopist to instillation of the photosensitizer and found no effect.<sup>25</sup> Like our report, prior reviews found no effect of fluorescent cystoscopy on risk of progression or mortality. Although prior reviews also found that fluorescent cystoscopy detected more bladder cancers on initial cystoscopy, this was not an assessed outcome for our review.

Our findings regarding the comparative effectiveness and harms of intravesical therapies are generally consistent with prior reviews that found intravesical therapy to be associated with decreased risk of bladder cancer recurrence versus no intravesical therapy<sup>35,36</sup> and found BCG to be associated with decreased risk of bladder cancer progression. Prior systematic reviews that focused on immediate single-instillation therapy also found intravesical therapy to be more effective than no intravesical therapy in reducing risk of bladder cancer recurrence, a conclusion consistent with our finding of no clear difference in risk estimates based on the type of instillation regimen.<sup>37-39</sup> Like our review, a prior systematic review found that maintenance therapy with BCG was associated with decreased risk of bladder cancer versus MMC, despite some differences in the trials that were included, definitions of maintenance therapy, and use of

individual patient data in the prior review.<sup>40</sup> Our findings are also consistent with prior systematic reviews that found BCG to be associated with decreased risk of bladder cancer versus epirubicin,<sup>41</sup> that the evidence on intravesical gemcitabine is limited,<sup>42</sup> and that the optimal dose and duration of intravesical therapy cannot be determined based on the available evidence.<sup>43</sup>

## **Applicability**

Some issues could impact the applicability of our findings. Some studies of diagnostic accuracy did not report results separately for patients undergoing evaluation of signs and symptoms of bladder cancer and those undergoing surveillance, although there is some evidence that diagnostic accuracy may vary based on the indication for testing. Studies of intravesical therapy varied in the doses used; the timing, number, frequency, and duration of instillations; and other factors (e.g., the BCG strain), making it difficult to reach conclusions that are widely generalizable. In addition, trials varied with regard to tumor characteristics in the patient populations evaluated. Another factor that potentially impacts applicability is that most studies focused on effects of intravesical therapy on recurrence of bladder cancer. Fewer trials evaluated more potentially serious distal outcomes, such as progression or mortality. A number of studies were conducted in Japan, where management of bladder cancer may differ from that in the United States. Treatment studies tended to exclude patients with significant comorbidities or poor general performance status, which could limit applicability to these populations. Very little information was available to determine whether diagnostic accuracy or treatment effects vary according to patient factors, such as age, sex, race/ethnicity, performance status, or comorbidities.

## **Implications for Clinical and Policy Decisionmaking**

Our review has implications for clinical and policy decisionmaking. As there are no studies evaluating effects of using urinary biomarkers for diagnosis or surveillance of bladder cancer on clinical outcomes, decisions regarding their use must necessarily be made on the basis of diagnostic test performance. Table B shows estimated probabilities for bladder cancer following use of urinary biomarkers, based on likelihood ratios calculated from pooled sensitivities and specificities. In populations with a pretest probability of 5 percent, the post-test probability increased to 16 to 24 percent following a positive result and decreased to 1.8 to 2.5 percent following a negative result. In settings with a pretest probability of 20 percent, the post-test probability increased to 37 to 60 percent following positive results and decreased to 8.0 to 11 percent following a negative result. Whether urinary biomarkers are sufficiently accurate to rule out bladder cancer and thereby reduce the need for cystoscopy depends on the ability of clinicians to estimate the pretest probability of disease and the acceptable threshold for a missed or delayed diagnosis. Use of urinary biomarkers in combination with urinary cytology increases the sensitivity for bladder cancer, but still misses about 10 percent of cases. Regarding fluorescent cystoscopy, studies have not shown an effect on progression or mortality, and trials that found reduced risk of recurrence may have been affected by performance bias. These findings might inform decisions regarding widespread adoption of fluorescent cystoscopy.

Our findings also have implications for use of intravesical therapy. Although intravesical therapy was associated with decreased risk of bladder cancer recurrence, there were no clear effects on bladder cancer–specific or all-cause mortality, and intravesical therapies were associated with local and systemic adverse events. Our findings are consistent with guidelines that recommend BCG as first-line therapy.<sup>10,44</sup> As no intravesical agent was more effective than

BCG at reducing risk of bladder cancer recurrence, BCG is the only intravesical agent associated with decreased risk of bladder cancer progression versus no intravesical therapy, and some evidence indicates that BCG is associated with decreased risk of bladder cancer recurrence versus other intravesical agents. However, BCG is also associated with a high risk of adverse events. Some evidence indicates that using lower than standard doses of BCG maintains effectiveness while reducing harms. Other evidence suggests that longer courses of therapy may be necessary for optimal effects, particularly in higher risk patients. Therefore, decisions to use intravesical therapy and regarding the intravesical agent, doses, and regimen selected should take into account the tradeoffs between potential benefits and harms. Benefits are likely to be higher in patients at higher risk for disease progression and harms.

**Table B. Post-test probability of bladder cancer using different biomarkers**

Urinary Biomarker	Pretest Probability of Bladder Cancer	Positive Likelihood Ratio (95% CI)	Post-Test Probability of HCC Following a Positive Test	Negative Likelihood Ratio (95% CI)	Post-Test Probability of HCC Following a Negative Test
Quantitative NMP22	5%	3.05 (2.28 to 4.10)	14%	0.40 (0.32 to 0.50)	2.1%
	20%	3.05 (2.28 to 4.10)	43%	0.40 (0.32 to 0.50)	9.1%
Qualitative NMP22	5%	4.89 (3.23 to 7.40)	20%	0.48 (0.33 to 0.71)	2.5%
	20%	4.89 (3.23 to 7.40)	55%	0.48 (0.33 to 0.71)	11%
Qualitative BTA	5%	2.80 (2.31 to 3.39)	13%	0.47 (0.30 to 0.55)	2.4%
	20%	2.80 (2.31 to 3.39)	41%	0.47 (0.30 to 0.55)	11%
Quantitative BTA	5%	2.52 (1.86 to 3.41)	12%	0.47 (0.37 to 0.61)	2.4%
	20%	2.52 (1.86 to 3.41)	39%	0.47 (0.37 to 0.61)	11%
FISH	5%	5.02 (2.93 to 8.60)	21%	0.42 (0.30 to 0.59)	2.2%
	20%	5.02 (2.93 to 8.60)	56%	0.42 (0.30 to 0.59)	9.5%
ImmunoCyt™	5%	3.49 (2.82 to 4.32)	16%	0.29 (0.20 to 0.41)	1.5%
	20%	3.49 (2.82 to 4.32)	47%	0.29 (0.20 to 0.41)	6.8%

BTA = bladder tumor antigen; CI = confidence interval; FISH = fluorescence in situ hybridization; HCC = hepatocellular carcinoma; NMP22 = nuclear matrix protein 22

## Limitations of the Review Process

Substantial statistical heterogeneity was present in most pooled analyses of diagnostic accuracy; this situation is common in meta-analyses of diagnostic accuracy.<sup>45-47</sup> As noted in the “Cochrane Handbook for Systematic Reviews of Diagnostic Test Accuracy,” “heterogeneity is to be expected in meta-analyses of diagnostic test accuracy.”<sup>47</sup> To address the anticipated heterogeneity, we used random-effects models to pool studies and stratified studies according to the reason that imaging was performed and the unit of analysis used. We also performed additional stratified and sensitivity analyses based on the reference standard used, study characteristics (such as country in which the study was conducted, factors related to risk of bias), patient characteristics, and technical factors related to the imaging tests under investigation.

Results were generally robust in sensitivity analyses, despite the heterogeneity. We also focused on evaluations of comparative test performance based on within-study comparisons of imaging modalities, which tended to be associated with less heterogeneity than pooled across-study estimates. A limitation of our analysis of within-group comparisons is that we had to treat the two compared groups as independent because we had aggregated data only. Individual patient-level data would be required to take into account the paired nature of the comparisons. Such correlations are generally positive and would be expected to result in more narrow CIs. Although it is possible that this could have caused us not to detect statistically significant differences, the point estimates indicated very little difference between tests.

We did not construct summary receiver operating characteristic curves. Almost all studies of a specific urinary biomarker used the same definition for a positive test, including tests based on a quantitative threshold. Estimates of sensitivity and specificity at different thresholds are needed to construct informative receiver operating characteristic curves.<sup>48</sup>

Statistical heterogeneity was also present in some analyses of intravesical therapies and fluorescent cystoscopy. To address this, we used the Dersimonian-Laird random-effects model to pool studies. The Dersimonian-Laird random-effects model may result in CIs that are too narrow when heterogeneity is present, particularly when the number of studies is small.<sup>24</sup> Therefore, we repeated analyses using the profile likelihood method, which resulted in similar findings. Regardless of the method used, meta-analyses based on small numbers of trials can underestimate statistical heterogeneity and must be interpreted with caution.<sup>24</sup> We also stratified trials according to factors such as risk-of-bias rating, dose, number of instillations, duration of followup, enrollment of patients with high-risk NMIBC, and other factors. Although statistical heterogeneity remained present in some analyses, with some unexplained outlier trials, results were generally robust.

We excluded non-English-language articles and did not search for studies published only as abstracts. Because of small numbers of trials for meta-analyses involving intravesical therapies, we did not formally assess for publication bias using statistical or graphical methods for assessing sample size effects, as research indicates that such methods can be seriously misleading in such situations.<sup>49,50</sup> For fluorescent cystoscopy, we found one relatively large trial that showed no effect on risk of recurrence versus white light cystoscopy, suggesting that publication bias could have impacted results.<sup>51</sup>

## **Limitations of the Evidence Base**

Several limitations of the evidence base limited our ability to reach strong conclusions with regard to several aspects of diagnosis and treatment of NMIBC. Other than quantitative NMP22 and qualitative BTA, urinary biomarkers were assessed in small numbers of studies (6 or fewer), resulting in less precise estimates. In addition, most of the evidence on comparative accuracy was indirect, as few studies directly compared the accuracy of two or more biomarkers against cystoscopy and histopathology.

For fluorescent cystoscopy, a limitation of the evidence base is that few trials reported effects on progression or mortality, and instead mostly focused on evaluating effects on recurrence. In addition, only one trial of fluorescent cystoscopy blinded the cystoscopist to whether the photosensitizer had been instilled, which may have an impact on assessments of recurrence because of performance bias related to knowledge of the type of initial cystoscopy performed.

A limitation of the evidence for all Key Questions addressed in our review is that very few trials were assessed as low risk of bias. Methodological shortcomings included failure to

adequately describe randomization and allocation concealment methods, and unblinded design. Findings would be stronger if more high-quality trials were available.

Other limitations include the lack of evidence on how use of urinary biomarkers impacts clinical outcomes (including harms), the evidence from only a single randomized trial on effects of radiation therapy for NMIBC, no trials on effects of using a risk-adapted approach, and no studies on how using different surveillance intervals impacts outcomes. Few studies evaluated effects of patient characteristics, such as age, sex, race/ethnicity, performance status, or comorbidities, on diagnostic test performance or effectiveness of intravesical therapy.

## **Research Gaps**

We identified a number of important research gaps. Given the increased sensitivity of urinary biomarkers with cytology, studies on how this combination impacts use of cystoscopy and subsequent clinical outcomes might be helpful for determining its role in diagnosis or surveillance. Randomized trials that adequately safeguard against performance bias associated with use of photosensitizers for fluorescent cystoscopy are needed to determine effects on recurrence, progression, and mortality. Additional head-to-head trials of intravesical therapies that use more standardized instillation regimens and doses, report outcomes in subgroups stratified by patient and tumor characteristics, and include long-term outcomes related to progression and mortality would help clarify optimal treatment strategies. Research is also needed to determine the effectiveness of risk-adapted approaches to guide selection of therapy, including use of nontraditional prognostic markers, effects of different surveillance intervals and protocols, and newer techniques such as electromotive administration of intravesical therapy.

## **Conclusions**

Urinary biomarkers are falsely negative in a substantial proportion of patients with bladder cancer, and additional research is needed to clarify advantages of fluorescent cystoscopy over white light cystoscopy. Intravesical therapy reduces risk of bladder cancer recurrence versus no intravesical therapy. BCG is the only intravesical therapy shown to be associated with decreased risk of bladder cancer progression, but it is associated with a high rate of adverse events.

# Introduction

## Background

### Nature and Burden of Non–Muscle-Invasive Bladder Cancer

Bladder cancer is the fourth most commonly diagnosed cancer in men and tenth most commonly diagnosed cancer in women in the United States.<sup>1</sup> The American Cancer Society estimates there will be 74,690 new cases of bladder cancer in the United States in 2014 (about 56,390 men and 18,300 women), and about 15,580 deaths due to bladder cancer (about 11,170 men and 4,410 women).<sup>1</sup> The lifetime probability of developing bladder cancer in the United States is approximately 3.8 percent in men and 1.2 percent in women; the incidence of bladder cancer is increasing in women. Bladder cancer occurs primarily in men older than 60 and roughly twice as frequently in white compared to black men,<sup>2</sup> though the number of deaths due to bladder cancer is similar, presumably due to delayed diagnosis in black men.

Bladder cancer is an important health problem, with no improvement in associated mortality since 1975.<sup>3</sup> Economic analyses have shown bladder cancer to be the costliest cancer to treat in the United States on a per capita basis, taking into account diagnostic testing, management, and long-term followup.<sup>4</sup> The most common risk factor for bladder cancer is cigarette smoking, though other risk factors include occupational exposures and family history. The most common symptom of bladder cancer is painless hematuria (blood in the urine).

Bladder cancer is staged based on the extent of penetration or invasion into the bladder wall and adjacent structures (Table 1).<sup>5</sup> Bladder cancers that have not invaded the bladder smooth muscle layer (stage classifications Tis [carcinoma in situ], Ta [noninvasive papillary carcinoma], and T1 [cancer that invades the subepithelial connective tissue]) are broadly grouped as non–muscle-invasive bladder cancers (NMIBC). Stage T2 cancers are muscle-invasive, and higher stage cancers invade beyond the muscle layer into surrounding fat (stage classification T3 bladder cancer) or beyond the fat into nearby organs or structures (stage classification T4 bladder cancer). Approximately 75 percent of newly diagnosed bladder cancers are NMIBC.<sup>6</sup> Individuals with NMIBC generally have a good prognosis, with 5-year survival rates higher than 88 percent.<sup>7</sup> However, as many as 70 percent of NMIBC tumors will recur after initial treatment, with a 10-20 percent risk of progression to invasive bladder cancer.<sup>6</sup> The likelihood of progression from NMIBC to muscle invasive cancer depends on the tumor grade (based on the degree of cell differentiation), the tumor stage, the size of the cancer, and whether the cancer is recurrent or multifocal.<sup>8</sup> Prognosis is poorer for patients with muscle-invasive bladder cancers (5-year survival rates from 63% to 15%).<sup>7</sup>

**Table 1. Bladder cancer tumor staging**

	<b>Cancer Stage</b>	<b>Description</b>
T stages (tumor)	CIS (also called Tis)	Flat, high grade, cancer cells are only present in the innermost layer of the bladder lining.
	Ta	The cancer is just in the innermost layer of the bladder lining
	T1	The cancer has started to grow into the connective tissue beneath the bladder lining
	T2	The cancer has grown through the connective tissue into the muscle
	T2a	The cancer has grown into the superficial muscle
	T2b	The cancer has grown into the deeper muscle
	T3	The cancer has grown through the muscle into the fat layer
	T3a	The cancer in the fat layer can only be seen under a microscope
	T3b	The cancer in the fat layer can be seen on tests, or felt by a doctor during an examination under anesthetic
	T4	The cancer has spread outside the bladder
	T4a	The cancer has spread to the prostate, womb (uterus), or vagina
	T4b	The cancer has spread to the wall of the pelvis or abdomen
N stages (lymph nodes)	N0	No cancer in any lymph nodes
	N1	There is cancer in one lymph node in the pelvis
	N2	There is cancer in more than one lymph node in the pelvis
	N3	There is cancer in one or more lymph nodes in the groin
M stages (metastasized)	M0	There are no signs of distant spread
	M1	The cancer has spread to distant parts of the body
1973 WHO grading urothelial papilloma	Grade 1 (G1)	Well differentiated
	Grade 2 (G2)	Moderately differentiated
	Grade 3 (G3)	Poorly differentiated
2004 WHO grading		Flat lesions
		Hyperplasia (flat lesion without atypia or papillary)
		Reactive atypia (flat lesion with atypia)
		Atypia of unknown significance
		Urothelial dysplasia
		Urothelial carcinoma <i>in situ</i>
		Papillary lesions
		Urothelial papilloma (which is a completely benign lesion)
		Papillary urothelial neoplasm of low malignant potential
		Low-grade papillary urothelial carcinoma
		High-grade papillary urothelial carcinoma

CIS = carcinoma in situ; WHO = World Health Organization

## Diagnosis and Surveillance of Bladder Cancer

A number of tests are available for screening, diagnosis, and staging of bladder cancer. Standard methods for identification of bladder cancer include urine dipstick and microscopic urinalysis (to detect hematuria) and urine cytology (to detect abnormal or cancerous cells in the urine), followed by imaging tests and cystoscopy.<sup>11</sup> Urine-based biomarkers have been developed as potential diagnostic alternatives or supplements to cytology, imaging, and cystoscopy.<sup>12</sup> A number of biomarkers have been evaluated in conjunction with cytology for diagnosis of bladder cancer, potentially reducing the need for cystoscopy. In addition to initial diagnosis and staging, diagnostic surveillance with cystoscopy and cytology is also performed following treatment, to identify patients with recurrence or progression of cancer. Urine-based

biomarker tests may also be used to help identify recurrence and need for cystoscopy during surveillance.

There are five diagnostic biomarker tests approved by the US Food and Drug Administration (FDA) for diagnosis or surveillance of bladder cancer: quantitative NMP22 (Alere NMP22<sup>®</sup>), qualitative NMP22 (BladderChek<sup>®</sup>), qualitative BTA (BTastat<sup>®</sup>), quantitative BTA (BTA TRAK<sup>®</sup>), fluorescence in situ hybridization (FISH, UroVysion<sup>®</sup>), and fluorescence immunohistochemistry (ImmunoCyt<sup>™</sup>, which uses monoclonal antibodies to test for carcinoembryonic antigens and mucin glycoproteins). The qualitative NMP22 and BTA tests can be used as point-of-care tests and the others are performed in a laboratory. The CxBladder<sup>™</sup> test, which tests for five specific mRNA biomarkers, is a “Laboratory Developed Test” that does not require FDA approval. A number of other biomarkers, including those based on detection of fibroblast growth factor receptor 3 (FGFR3); cytokeratin fragments (e.g., CYFRA 21-1, TPA, TPS); survivin; telomerase; vascular endothelial growth factor (VEGF); aurora kinase, or metalloproteinases (MMP-2 and MMP-9) have also been developed, but are not FDA-approved. The large number of available tests and testing strategies and potential trade-offs in diagnostic accuracy, risks, and patient preferences pose significant challenges in determining optimal testing and monitoring strategies. Tests with high false positive rates could lead to unnecessary invasive procedures for further evaluation and tests with high false negative rates could lead to missed diagnoses.

## **Interventions and Outcomes For Non–Muscle-Invasive Bladder Cancer**

Once bladder cancer has been diagnosed, a number of factors affect prognosis and treatment options. These include the stage of the cancer, tumor grade, whether the tumor is an initial tumor or a recurrence, the number and size of tumors, the patient’s age and general health, and other factors. The main treatment for NMIBC is local resection with transurethral resection of the bladder tumor (TURBT), often with adjuvant intravesical therapy to destroy residual tumor cells using chemotherapeutic agents (e.g., mitomycin C [MMC], apaziquone, paclitaxel, gemcitabine, thiotepa, valrubicin, doxorubicin, epirubicin), bacillus Calmette-Guérin (BCG), or interferon immunotherapy.<sup>13</sup> All of these treatments are FDA-approved and available in the United States. Electromotive drug administration is a method for enhancing the effectiveness of intravesical chemotherapy that is increasingly used, especially in Europe. Clinical trials of electromotive drug administration of intravesical therapy are ongoing in the United States, but the method is not widely available or used in the United States, and is not FDA-approved for this purpose.

Post-TURBT adjuvant intravesical therapy is associated with potential local (e.g., dysuria frequency, and hematuria) and systemic side effects. However, not using adjuvant intravesical therapy may increase the risk of bladder cancer recurrence or progression, particularly in patients with higher risk lesions. The European Association of Urology advocates an assessed risk-adapted approach to treatment decisionmaking, based on prognostic factors such as tumor grade, tumor stage, and the number and size of tumors.<sup>14</sup> This approach, which stratifies patients into three risk groups based on the presence of risk factors, helps identify patients in the intermediate and high risk groups who are more likely to benefit from intravesical therapy.

## **Rationale for Evidence Review**

The purpose of this report is to review the currently available evidence on the comparative effectiveness of diagnostic tests and treatments for NMIBC. Although updated guidelines for the treatment and followup of NMIBC from the European Association of Urology were published in 2013,<sup>8</sup> the literature continues to evolve, with much of the new evidence focusing on diagnostic techniques such as fluorescence cystoscopy or urine-based biomarkers, and treatments with intravesical therapy alternatives to MMC and BCG. A systematic evidence review that includes recently published research may provide a better understanding of the comparative effectiveness of currently available approaches to diagnosis, treatment, and post-treatment surveillance for NMIBC. The systematic review may be used to update existing clinical recommendations that are several years old or may be out-of-date due to the development of new technologies and therapies.

## **Scope of Review and Key Questions**

This topic was nominated for review by the American Urological Association and focuses on diagnosis of bladder cancer and treatment of NMIBC. The Key Questions and analytic framework used to guide this report are shown below. The analytic framework (Figure 1) shows the scope of this review, including the target population, interventions, comparisons, and health outcomes we examined.

The list of Key Questions follows.

**Key Question 1.** What is the diagnostic accuracy of various urinary biomarkers compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging) in (1) people with signs or symptoms warranting evaluation for possible bladder cancer or (2) people undergoing surveillance for previously treated bladder cancer?

- a. Does the diagnostic accuracy differ according to patient characteristics (e.g., age, sex, race/ethnicity) or according to the nature of the presenting signs or symptoms?

**Key Question 2.** For patients with non–muscle-invasive bladder cancer, does the use of a formal risk-adapted assessment approach to treatment decisions (e.g., based on Guidelines of the European Association of Urology or on urinary biomarker tests) decrease mortality or improve other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with treatment not guided by a formal assessed risk-adapted approach?

**Key Question 3.** For patients with non–muscle-invasive bladder cancer treated with transurethral resection of bladder tumor, what is the effectiveness of various intravesical chemotherapeutic or immunotherapeutic agents for decreasing mortality or improving other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with TURBT alone?

- a. What is the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents, as monotherapy or in combination?
- b. Does the comparative effectiveness differ according to tumor characteristics, such as stage, grade, size, multiplicity, whether the tumor is primary or recurrent, or molecular/genetic markers?
- c. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities?
- d. Does the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents differ according to dosing frequency, duration of treatment, and/or the timing of administration relative to TURBT?

**Key Question 4.** For patients with high-risk non–muscle-invasive bladder cancer treated with TURBT, what is the effectiveness of external beam radiation therapy (either alone or with systemic chemotherapy/immunotherapy) for decreasing mortality or improving other outcomes compared with intravesical chemotherapy/immunotherapy alone or cystectomy?

**Key Question 5.** In surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of various urinary biomarkers to decrease mortality or improve other outcomes compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging)?

- a. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers?
- b. Does the comparative effectiveness differ according to the treatment used (i.e., specific chemotherapeutic or immunotherapeutic agents and/or TURBT)?
- c. Does the comparative effectiveness differ according to the length of surveillance intervals?

- d. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, or race/ethnicity?

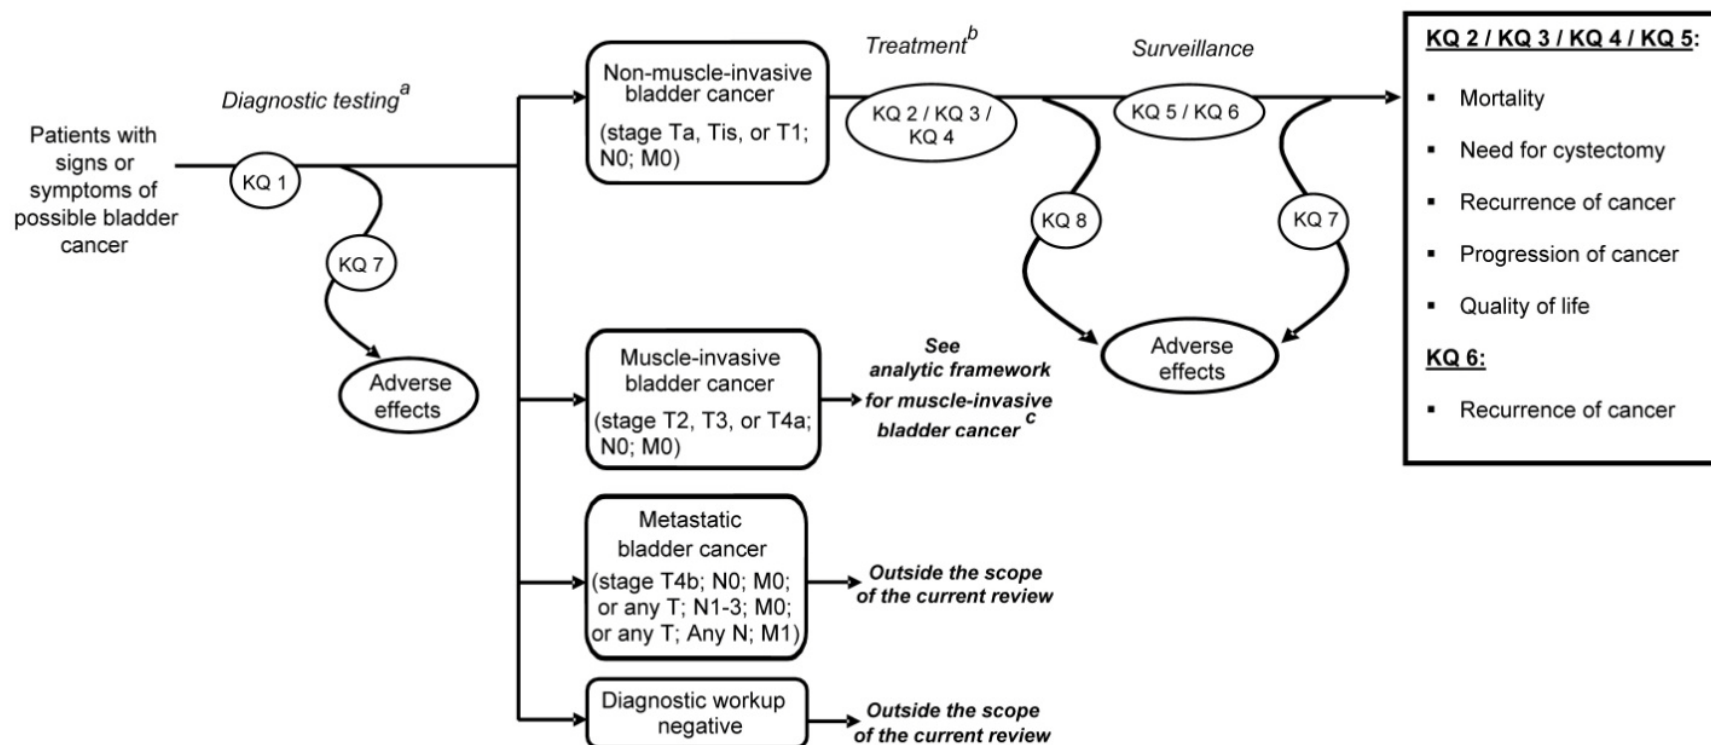

**Key Question 6.** For initial diagnosis or surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of blue light or other methods of augmented cystoscopy compared with standard cystoscopy for recurrence rates, progression of bladder cancer, mortality, or other clinical outcomes?

**Key Question 7.** What are the comparative adverse effects of various tests for diagnosis and post-treatment surveillance of bladder cancer, including urinary biomarkers, cytology, and cystoscopy?

**Key Question 8.** What are the comparative adverse effects of various treatments for non–muscle-invasive bladder cancer, including intravesical chemotherapeutic or immunotherapeutic agents and TURBT?

- a. How do adverse effects of treatment vary by patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities such as chronic kidney disease?

Figure 1. Analytic framework

KQ = Key Question. Cancer stages shown are the TNM (tumor, node, metastasis) classification.

<sup>a</sup>Urinary biomarkers of interest are restricted to tests that are approved for diagnosis of bladder cancer by the U.S. Food and Drug Administration (BTastat<sup>®</sup> [bladder tumor antigen], Alere NMP22<sup>®</sup>, BladderChek<sup>®</sup> [nuclear matrix protein 22], UroVysion<sup>®</sup> [fluorescence in situ hybridization], and ImmunoCyt<sup>™</sup> [immunocytology]) or available in the United States and classified as a Laboratory Developed Test by the Food and Drug Administration (CxBladder<sup>™</sup>).

<sup>b</sup>Chemotherapeutic and immunotherapeutic agents of interest include mitomycin C, apaziquone, paclitaxel, gemcitabine, thiotepa, epirubicin, valrubicin, doxorubicin, bacillus Calmette-Guérin, and interferon.

<sup>c</sup>Muscle-Invasive Bladder Cancer Comparative Effectiveness Review: Chou R, Selph S, Buckley D, et al. Treatment of Nonmetastatic Muscle-Invasive Bladder Cancer. Comparative Effectiveness Review No. 152. (Prepared by the Pacific Northwest Evidence-based Practice Center under Contract No. 290-2012-00014-1.) AHRQ Publication No. 15-EHC015-EF. Rockville, MD: Agency for Healthcare Research and Quality; June 2015. [www.effectivehealthcare.ahrq.gov/reports/final.cfm](http://www.effectivehealthcare.ahrq.gov/reports/final.cfm).

## Methods

This comparative effectiveness review (CER) follows the methods suggested in the Agency for Healthcare Research and Quality (AHRQ) “Methods Guide for Effectiveness and Comparative Effectiveness Reviews” (hereafter AHRQ Methods Guide).<sup>15</sup> All methods were determined a priori.

### Topic Development and Refinement

AHRQ initially received this topic as a nomination via the Effective Healthcare Web site (<http://www.effectivehealthcare.ahrq.gov/index.cfm/submit-a-suggestion-for-research/>). The Scientific Resource Center developed preliminary Key Questions based on input from the topic nominator. The Evidence-based Practice Center revised the Key Questions and developed eligibility criteria to identify the populations, interventions, comparators, outcomes, timing, and study designs (PICOTS) of interest. The Evidence-based Practice Center further refined the Key Questions and PICOTS based on input from interviews with eight Key Informants. Key Informants included experts in urology (including experts in urinary biomarkers and urologic oncology), medical oncology, and radiation oncology, as well as patient representatives and payers. Key Informants disclosed financial and other conflicts of interest prior to participation. The AHRQ Task Order Officer and the investigators reviewed the disclosures and determined that the Key Informants had no conflicts of interest that precluded participation. The Key Questions were posted for public comment from February 6, 2014 through February 26, 2014, and comments were received from four individuals.

After reviewing the public comments and obtaining additional input from a Technical Expert Panel (TEP) convened for this report, the research team revised the Key Questions. The TEP consisted of eight experts, specializing in urology (including urinary biomarkers and urologic oncology), radiation oncology, and medical oncology. The procedure for reviewing potential conflicts of interests of TEP members was similar to the procedure used for the Key Informants. The research team developed the final protocol with input from the TEP and AHRQ and was posted on the AHRQ Web site on July 21, 2014 ([www.effectivehealthcare.ahrq.gov/search-for-guides-reviews-and-reports/?pageaction=displayproduct&productid=1940](http://www.effectivehealthcare.ahrq.gov/search-for-guides-reviews-and-reports/?pageaction=displayproduct&productid=1940)). The protocol was also registered in the PROSPERO international database of prospectively registered systematic reviews.

### Searching for the Evidence

A research librarian experienced in conducting literature searches for CERs searched in Ovid MEDLINE (January 1990–October 2014), Cochrane Central Register of Controlled Trials (through September 2014), Cochrane Database of Systematic Reviews (through September 2014), Health Technology Assessment (through 3<sup>rd</sup> Quarter, 2014), National Health Sciences Economic Evaluation Database (through 3<sup>rd</sup> Quarter, 2014), and Database of Abstracts of Reviews of Effects (through 3<sup>rd</sup> Quarter, 2014) to capture both published and grey literature. See Appendix A for the full search strategies. We searched for unpublished studies in clinical trial registries (ClinicalTrials.gov, Current Controlled Trials, ClinicalStudyResults.org and the WHO International Clinical Trials Registry Platform) and regulatory documents (Drugs@FDA.gov and FDA Medical Devices Registration and Listing). Reference lists of relevant studies and previous systematic reviews were hand-searched for additional studies, including studies published prior to 1990. Scientific information packets were solicited from drug and device manufacturers and

via a notice published in the Federal Register that invited interested parties to submit relevant published and unpublished studies using the publicly accessible AHRQ Effective Health Care online scientific information packet portal.

Library searches were updated while the draft report was posted for public comment. Literature identified during the update search was assessed following the same process of dual review as for studies identified during the initial searches. New literature identified for inclusion was incorporated before the final submission of the report.

## **Study Selection**

We developed criteria for inclusion and exclusion of studies based on the Key Questions and PICOTS approach, in accordance with the AHRQ Methods Guide.<sup>15</sup> Inclusion and exclusion criteria are summarized below and available in more detail in Appendix B. Abstracts were reviewed by two investigators, and all citations deemed appropriate for inclusion by at least one of the reviewers was retrieved. Two investigators independently reviewed all full-text articles for inclusion. Discrepancies were resolved by discussion and consensus. A list of the included studies can be found in Appendix C; excluded studies and primary reason for exclusion can be found in Appendix D.

## **Population and Condition of Interest**

For Key Questions related to diagnosis, we included studies of adults with signs or symptoms of possible bladder cancer (e.g., macroscopic or microscopic hematuria, irritative voiding symptoms) or undergoing surveillance following treatment for bladder cancer. For Key Questions related to treatment of non-muscle-invasive bladder cancer (NMIBC), we included studies of adults with NMIBC (defined as TNM stages Ta, Tis, or T1; N0; M0) undergoing treatment. Key Question 4 focused on adults with high-risk NMIBC.

## **Interventions, Comparisons, and Study Designs of Interest**

We included studies of US Food and Drug Administration (FDA)-approved urinary biomarkers for the diagnosis of bladder cancer (quantitative or qualitative NMP22, qualitative or quantitative BTA, FISH, and ImmunoCyt<sup>TM</sup>) or available in the United States and classified as a Laboratory Developed Test by the FDA (CxBladder<sup>TM</sup>). We excluded studies of diagnostic accuracy of other biomarkers or studies of included biomarkers that did not evaluate diagnostic accuracy of biomarkers against standard diagnostic methods (cystoscopy and histopathology). For cystoscopic methods, we included studies of fluorescent cystoscopy following intravesical instillation of a photosensitizing agent or other methods of augmented cystoscopy (e.g., narrow band imaging) for the initial diagnosis or surveillance of bladder cancer compared with standard (white light) cystoscopy.

For treatments, we include studies of intravesical therapies (mitomycin C [MMC], apaziquone, paclitaxel, gemcitabine, thiotepa, valrubicin, doxorubicin, epirubicin, bacillus Calmette-Guérin [BCG] and interferon) and external beam radiation therapy with or without systemic chemotherapy or immunotherapy versus transurethral resection of the bladder tumor (TURBT), other intravesical therapies, or cystectomy. We also included studies that compared different dosing regimens, different surveillance intervals, and risk adapted versus other approaches. We also included studies on the effects of patient and tumor characteristics on estimates of effectiveness.

For all Key Questions, we included randomized trials and cohort studies with concurrent controls, when randomized trials were not available. For diagnostic accuracy, we also included cross-sectional studies. We excluded uncontrolled observational studies, case-control studies, case series, and case reports, as these studies are less informative than studies with a control group. For studies on diagnostic accuracy of urinary biomarkers, case-control studies were defined as studies that selected patients known to have bladder cancer [cases] and patients known to not have bladder cancer [controls].<sup>16</sup> We did not include systematic reviews, though we reviewed reference lists for relevant studies.

## **Outcomes of Interest**

For diagnostic accuracy of urinary biomarkers, we evaluated sensitivity, specificity, predictive values, and likelihood ratios, using cystoscopy with biopsy as the reference standard. Clinical outcomes for trials of diagnostic methods and treatments were mortality, need for cystectomy, progression to muscle invasive bladder cancer, bladder cancer recurrence, and quality of life. We also evaluated adverse effects of diagnostic testing (e.g., false-positives, labeling, anxiety, and complications of cystoscopy) and adverse effects of treatment (e.g., cystitis, urinary urgency, urinary frequency, incontinence, hematuria, pain, and urosepsis, myelosuppression).

## **Timing and Setting of Interest**

For all Key Questions, we included studies conducted in inpatient or outpatient settings, with any duration of followup.

## **Data Extraction and Data Management**

For treatment studies, we extracted the following information into evidence tables: study design, setting, inclusion and exclusion criteria, dose and duration of treatment for experimental and control groups, duration of followup, number of subjects screened, eligible and enrolled, population characteristics (including age, race/ethnicity, sex, tumor stage and grade, and functional status), results, adverse events, withdrawals due to adverse events, and sources of funding. We calculated relative risks and associated 95% confidence intervals (CI) based on the information provided (sample sizes and incidence of outcomes in each intervention group). We noted discrepancies between calculated and reported results when present.

For diagnostic accuracy studies, we abstracted the following information: setting, screening test or tests, method of data collection, reference standard, inclusion criteria, population characteristics (including age, sex, race/ethnicity, smoking status, signs or symptoms, and prior bladder cancer stage or grade), proportion of individuals with bladder cancer, bladder cancer stage and grade, definition of a positive screening exam, proportion of individuals unexaminable by the screening test, proportion who did not undergo reference standard test, results, and sources of funding. We attempted to create two-by-two tables from information provided (sample size, prevalence, sensitivity, and specificity) and compared calculated measures of diagnostic accuracy based on the two-by-two tables with reported results. We noted discrepancies between calculated and reported results when present. When reported, we also recorded the area under the receiver operating characteristic curve.<sup>17,18</sup>

Data extraction for each study was completed by one investigator and independently reviewed for accuracy and completeness by a second investigator. See Appendix E for evidence tables with extracted data.

## **Assessment of the Risk of Bias of Individual Studies**

We assessed the risk of bias for randomized trials and observational studies using criteria adapted from those developed by the U.S. Preventive Services Task Force.<sup>19</sup> Studies of diagnostic accuracy were rated using criteria adapted from QUADAS-2.<sup>16</sup> These criteria were applied in conjunction with the approaches recommended in the AHRQ Methods Guide for medical interventions and the AHRQ Methods Guide for Medical Test Reviews.<sup>15,20</sup>

Two investigators independently assessed the risk of bias of each study. Discrepancies were resolved through discussion and consensus.

Each study was rated as “low,” “medium,” or “high” risk of bias.<sup>15</sup> We rated the quality of each randomized trial based on the methods used for randomization, allocation concealment, and blinding; the similarity of compared groups at baseline; whether attrition was adequately reported and acceptable; similarity in use of cointerventions; compliance to allocated treatments; the use of intent-to-treat analysis; and avoidance of selective outcomes reporting.<sup>19</sup>

We rated the quality of each cohort study based on whether it enrolled a consecutive or random sample of patients meeting inclusion criteria; whether it evaluated comparable groups; whether rates of loss to followup were reported and acceptable; whether it used accurate methods for ascertaining exposures, potential confounders, and outcomes; and whether it performed adjustment for important potential confounders.<sup>19</sup>

We rated the quality of each study on diagnostic accuracy based on whether it evaluated a consecutive or random sample of patients meeting predefined criteria, whether the index test was performed in all patients, whether the index test results were interpreted without knowledge of the reference standard, whether a prespecified threshold was used to define a positive index test, whether the reference standard was interpreted without knowledge of the reference standard, whether there was an appropriate interval between the index test and the reference standard, whether the same reference standard was applied in all patients, and whether all patients were included in the analysis.<sup>16,20</sup>

Studies rated “low risk of bias” were considered to have no more than very minor methodological shortcomings and their results are likely to be valid. Studies rated “medium risk of bias” have some methodological shortcomings, but no flaw or combination of flaws judged likely to cause major bias. In some cases, the article did not report important information, making it difficult to assess its methods or potential limitations. The “medium risk of bias” category is broad and studies with this rating vary in their strengths and weaknesses; the results of some studies assessed to have medium risk of bias are likely to be valid, while others may be only possibly valid. Studies rated “high risk of bias” have significant flaws that may invalidate the results. They have a serious or “fatal” flaw or combination of flaws in design, analysis, or reporting; large amounts of missing information (including publication of only preliminary results in a subgroup of patients randomized); or serious discrepancies in reporting. An example of a fatally flawed study would be one with very high loss to followup (e.g., >50%), failure to perform intention-to-treat analysis, lack of blinding and failure to adequately describe randomization procedures. The results of these studies are at least as likely to reflect flaws in the study design as the differences between the compared interventions. We did not exclude studies

rated as having high risk of bias *a priori*, but they were considered the least reliable when synthesizing the evidence, particularly when discrepancies between studies were present.

For further details about the assessment of the risk of bias see Appendix F.

## Assessing Applicability

We recorded factors important for understanding the applicability of studies, such as whether the publication adequately described the study sample, the country in which the study was conducted, the characteristics of the patient sample (e.g., age, sex, race/ethnicity, risk factors for bladder cancer, presenting symptoms, and medical comorbidities), tumor characteristics (e.g., stage and grade, primary or recurrent, unifocal or multifocal lesions), the characteristics of the diagnostic tests (e.g., specific test evaluated and cutoffs used) and interventions (e.g., treatment dose, duration and interval) used, and the magnitude of effects on clinical outcomes.<sup>15</sup> We also recorded the funding source and role of the sponsor.

Applicability depends on the particular question and the needs of the user of the review. There is no generally accepted universal rating system for applicability. In addition, applicability depends in part on context. Therefore, a rating of applicability (such as “high” or “low”) was not assigned because applicability may differ based on the user of this report.

## Data Synthesis

For studies on diagnostic accuracy of urinary biomarkers, we performed meta-analyses to help summarize data and obtain more precise estimates.<sup>21</sup> All quantitative analyses were conducted using SAS<sup>®</sup> 10.0 (SAS Institute Inc., Cary, NC). We used a bivariate logistic mixed effects model<sup>22</sup> to analyze sensitivity and specificity, incorporating the correlation between sensitivity and specificity. We assumed random effects across studies with a bivariate normal distribution for sensitivity and specificity, and heterogeneity among the studies was measured based on the random effect variance ( $\tau^2$ ). The advantage of using a logistic mixed effects model is that it handles sparse data better and does not need to assume an ad hoc continuity correction when a study has zero events.<sup>22</sup> When few studies were available for an analysis, we used the moment estimates of correlation between sensitivity and specificity in the bivariate model. We calculated positive likelihood ratio (LR+) and negative likelihood ratio (LR-) using the summarized sensitivity and specificity.<sup>23,24</sup> Because studies of a particular biomarker generally used the same definition for a positive test, we did not attempt to plot summary receiver operating characteristic (ROC), which are based on estimates of sensitivity and specificity at different thresholds.<sup>25</sup> For head-to-head comparisons, we used the same bivariate logistic mixed effects model as described above, but added an indicator variable for imaging modalities (equivalent to a meta-regression approach).

We conducted analyses for each biomarker based on data from all patients who underwent testing, as well as stratified according to whether testing was performed for evaluation of signs or symptoms of bladder cancer or for surveillance for previously treated bladder cancer. We also performed analyses stratified according to aspects of study design (retrospective or prospective design, use of prespecified threshold to define a positive test), risk of bias (overall risk of bias rating and whether the study performed blinded to the results of the index test), and setting (based on the country in which the study was performed), and in subgroups defined by tumor grade and stage. We performed separate analyses on the subset of studies that directly compared two or more imaging modalities or techniques in the same population against a common reference standard. Research indicates that results based on such direct comparisons differ from

results based on noncomparative studies, and may be better suited for evaluating comparative diagnostic test performance.<sup>26</sup>

We also conducted meta-analyses on trials of intravesical therapy that reported effects on clinical outcomes and were homogeneous enough to provide a meaningful combined estimate. We used the Dersimonian-Laird random effects method using SAS software, Version 10.0 (SAS Institute Inc., Cary, NC).<sup>27</sup> We assessed the presence of statistical heterogeneity among the studies using the standard Cochran's chi-square test, and the magnitude of heterogeneity by using the  $I^2$  statistic.<sup>28</sup> When statistical heterogeneity was present, we performed sensitivity analyses by conducting meta-analysis using the profile likelihood method.<sup>29</sup> We also performed sensitivity and subgroup analyses based on ratings for risk of bias, dose of intravesical therapy, inclusion of high-risk patients, and duration of followup. We also stratified trials according to the type of instillation regimen, classified as single instillation, induction therapy (treatment for 4 to 8 weeks), maintenance therapy (treatment for longer than 8 weeks), or other. We calculated pooled relative risks for the dichotomous outcomes bladder cancer recurrence, bladder cancer progression, all-cause mortality, bladder cancer mortality, and local and systemic adverse events. Similar analyses were performed for trials of augmented cystoscopy (fluorescent light or narrow band imaging) versus white light cystoscopy.

## **Grading the Strength of Evidence for Each Key Question**

We assessed the strength of evidence for each Key Question and outcome using the approach described in the AHRQ Methods Guide,<sup>15</sup> based on the overall quality of each body of evidence, the risk of bias (graded low, medium, or high); the consistency of results across studies (graded consistent, inconsistent, or unable to determine when only one study was available); the directness of the evidence linking the intervention and health outcomes (graded direct or indirect); the precision of the estimate of effect, based on the number and size of studies and confidence intervals for the estimates (graded precise or imprecise); and reporting bias (suspected of undetected)

Assessments of reporting bias were based on whether studies defined and reported primary outcomes, identification of relevant unpublished studies, and when available, by comparing published results to results reported in trial registries.

We graded the strength of evidence for each Key Question using the four key categories recommended in the AHRQ Methods Guide.<sup>15</sup> A “high” grade indicates high confidence that the evidence reflects the true effect and that further research is very unlikely to change our confidence in the estimate of effect. A “moderate” grade indicates moderate confidence that the evidence reflects the true effect and further research may change our confidence in the estimate of effect and may change the estimate. A “low” grade indicates low confidence that the evidence reflects the true effect and further research is likely to change the confidence in the estimate of effect and is likely to change the estimate. An “insufficient” grade indicates evidence either is unavailable or is too limited to permit any conclusion, due to the availability of only poor-quality studies, extreme inconsistency, or extreme imprecision.

See Appendix G for the strength of evidence tables.

## **Peer Review and Public Commentary**

Experts in urology (including experts in urologic oncology and urinary biomarkers), medical oncology, and radiation oncology, were invited to provide peer review of the draft report. The AHRQ Task Order Officer and an Evidence-based Practice Center Associate Editor also

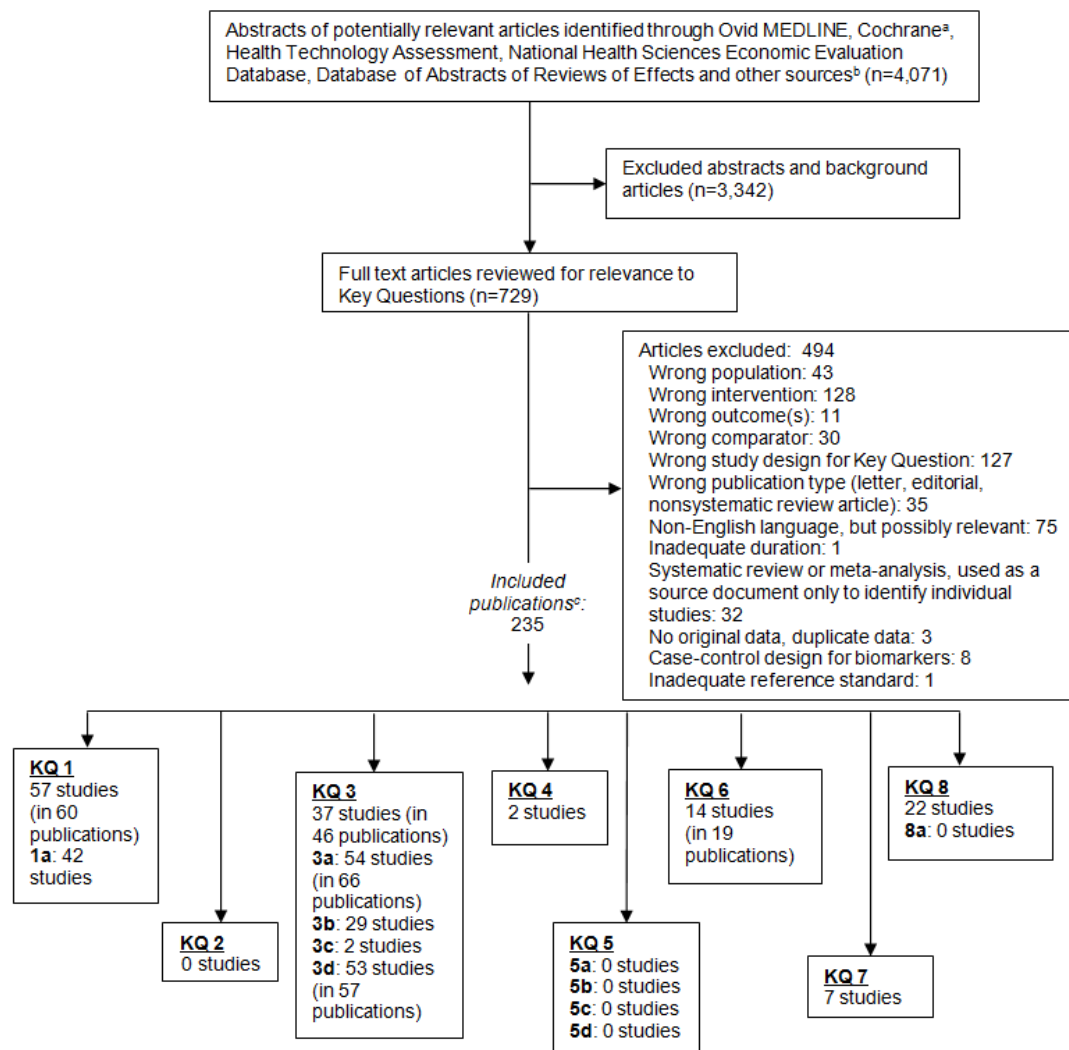

provided comments and editorial review. The draft report was posted on the AHRQ Web site for 4 weeks for public comment. A disposition of comments report with authors' responses to the peer and public review comments will be posted after publication of the final CER on the public Web site.

# Results

## Results of Literature Searches

The search and selection of articles are summarized in the literature flow diagram (Figure 2). Database searches resulted in 4,071 potentially relevant articles. After dual review of abstracts and titles, 729 articles were selected for full-text dual review and 201 studies (in 235 publications) were determined to meet inclusion criteria and were included in this review. Data extraction and risk of bias assessment tables for all included studies are available in Appendixes E and F.

**Figure 2. Literature flow diagram**

KQ = Key Question

<sup>a</sup> Cochrane databases include the Cochrane Central Register of Controlled Trials and the Cochrane Database of Systematic Reviews.

<sup>b</sup> Other sources include prior reports, reference lists of relevant articles, systematic reviews, etc.

<sup>c</sup> Some studies have multiple publications and some are included for more than one Key Question.

**Key Question 1.** What is the diagnostic accuracy of various urinary biomarkers compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging) in (1) people with signs or symptoms warranting evaluation for possible bladder cancer or (2) people undergoing surveillance for previously treated bladder cancer?

## **Key Points**

- Quantitative NMP22: Sensitivity was 0.69 (95% CI 0.62 to 0.75) and specificity 0.77 (95% CI 0.70 to 0.83), based on 19 studies, for a positive likelihood ratio of 3.05 (95% CI 2.28 to 4.10) and negative likelihood ratio of 0.40 (95% CI 0.32 to 0.50) (SOE: moderate)
  - For evaluation of symptoms: Sensitivity was 0.67 (95% CI 0.55 to 0.77; 9 studies) and specificity 0.84 (95% CI 0.75 to 0.90; 7 studies).
  - For surveillance: Sensitivity was 0.61 (95% CI 0.49 to 0.71; 10 studies) and specificity 0.71 (95% CI 0.60 to 0.81; 8 studies).
- Qualitative NMP22: Sensitivity of qualitative NMP22 was 0.58 (95% CI 0.39 to 0.75) and specificity 0.88 (95% CI 0.78 to 0.94), based on four studies, for a positive likelihood ratio of 4.89 (95% CI 3.23 to 7.40) and negative likelihood ratio of 0.48 (95% CI 0.33 to 0.71) (SOE: low).
  - For evaluation of symptoms: Sensitivity was 0.47 (95% CI 0.33 to 0.61) and specificity 0.93 (95% CI 0.81 to 0.97), based on two studies.
  - For surveillance: Sensitivity was 0.70 (95% CI 0.40 to 0.89) and specificity 0.83 (95% CI 0.75 to 0.89), based on two studies.
- Qualitative BTA: Sensitivity was 0.64 (95% CI 0.58 to 0.69, 22 studies) and specificity 0.77 (95% CI 0.73 to 0.81, 21 studies), for a positive likelihood ratio of 2.80 (95% CI 2.31 to 3.39) and negative likelihood ratio of 0.47 (95% CI 0.30 to 0.55) (SOE: moderate).
  - For evaluation of symptoms: Sensitivity was 0.76 (95% CI 0.67 to 0.83; 8 studies), and specificity 0.78 (95% CI 0.66 to 0.87; 6 studies).
  - For surveillance: Sensitivity was 0.60 (95% CI 0.55 to 0.65; 11 studies) and specificity 0.76 (95% CI 0.69 to 0.83; 8 studies).
- Quantitative BTA: Sensitivity was 0.65 (95% CI 0.54 to 0.75) and specificity 0.74 (95% CI 0.64 to 0.82), based on four studies, for a positive likelihood ratio of 2.52 (95% CI 1.86 to 3.41) and negative likelihood ratio of 0.47 (95% CI 0.37 to 0.61) (SOE: low).
  - For evaluation of symptoms: Sensitivity was 0.76 (95% CI 0.61 to 0.87) and specificity 0.53 (95% CI 0.38 to 0.68), based on one study.
  - For surveillance: Sensitivity was 0.58 (95% CI 0.46 to 0.69) and specificity 0.79 (95% CI 0.72 to 0.85), based on two studies.
- FISH: Sensitivity was 0.63 (95% CI 0.50 to 0.75) and specificity 0.87 (95% CI 0.79 to 0.93), based on 11 studies, for a positive likelihood ratio of 5.02 (95% CI 2.93 to 8.60) and negative likelihood ratio of 0.42 (95% CI 0.30 to 0.59) (SOE: moderate).
  - For evaluation of symptoms: Sensitivity was 0.73 (95% CI 0.50 to 0.88) and specificity was 0.95 (0.87 to 0.98), based on two studies, for a positive likelihood ratio of 14.2 (95% CI 5.2 to 39) and negative likelihood ratio of 0.29 (95% CI 0.14 to 0.60).
  - For surveillance: Sensitivity was 0.55 (95% CI 0.36 to 0.72; 7 studies) and specificity was 0.80 (95% CI 0.66 to 0.89; 6 studies).

- ImmunoCyt: Sensitivity was 0.78 (95% CI 0.68 to 0.85) and specificity 0.78 (95% CI 0.72 to 0.82), based on 14 studies, for a positive likelihood ratio of 3.49 (95% 2.82 to 4.32) and negative likelihood ratio of 0.29 (95% CI 0.20 to 0.41) (SOE: moderate).
  - For evaluation of symptoms: Sensitivity was 0.85 (95% CI 0.78 to 0.90; 6 studies) and specificity was 0.83 (95% CI 0.77 to 0.87; 7 studies).
  - For surveillance: Sensitivity was 0.75 (95% CI 0.64 to 0.83; 7 studies) and specificity was 0.76 (95% CI 0.70 to 0.81; 8 studies).
- CxBladder: Sensitivity was 0.82 (95% CI 0.70 to 0.90) and specificity of 0.85 (95% CI 0.81 to 0.88) for evaluation of symptoms, based on one study, for a positive likelihood ratio of 5.53 (95% CI 4.28 to 7.15) and negative likelihood ratio of 0.21 (95% CI 0.13 to 0.36) (SOE: low).
- Direct (within-study) comparisons
  - There was no difference between quantitative NMP22 (cutoff >10 U/mL) versus qualitative BTA in sensitivity (0.69, 95% CI 0.62 to 0.76 vs. 0.66, 95% CI 0.59 to 0.73, for a difference of 0.03, 95% CI -0.04 to 0.10) or specificity (0.73, 95% CI 0.62 to 0.82 vs. 0.76, 95% CI 0.66 to 0.84, for a difference of 0.03, 95% CI -0.08 to 0.01), based on seven studies (SOE: moderate).
  - ImmunoCyt was associated with higher sensitivity than FISH (0.71, 95% CI 0.54 to 0.84 vs. 0.61, 95% CI 0.43 to 0.76, for a difference of 0.11, 95% CI 0.001 to 0.21) but lower specificity (0.71, 95% CI 0.62 to 0.79 vs. 0.79, 95% CI 0.71 to 0.85, for a difference of -0.08, 95% CI -0.15 to -0.001), based on three studies (SOE: low).
  - Evidence for other head-to-head comparisons of urinary biomarkers was based on small numbers of studies with imprecise estimates and methodological shortcomings, precluding reliable conclusions regarding comparative test performance (SOE: insufficient).
  - Sixteen studies found sensitivity of various urinary biomarkers plus cytology associated with higher sensitivity than the urinary biomarker alone (0.81, 95% CI 0.75 to 0.86 vs. 0.69, 95% CI 0.61 to 0.76, for a difference of 0.13, 95% CI 0.08 to 0.17), with no difference in specificity (SOE: moderate).

## Detailed Synthesis

Fifty-seven studies in 60 publications evaluated the diagnostic accuracy of urinary biomarkers for diagnosis of bladder cancer (Table 2, Appendix E1, F1).<sup>30-89</sup> Quantitative NMP22 was evaluated in 19 studies,<sup>30,32,33,39,52,53,57,60,61,63,65-67,72,73,75,83,87,89</sup> 4 studies in 5 publications evaluated qualitative NMP 22,<sup>35,36,38,47,52</sup> 23 studies in 24 publications evaluated qualitative BTA,<sup>32,33,39-42,44,45,49,51,56,58-60,62,64,67-70,77,80,83,87,89</sup> 4 studies evaluated quantitative BTA,<sup>34,42,69,83</sup> 10 studies evaluated FISH,<sup>37,43,55,62,71,75,76,84,85,87</sup> 13 studies in 14 publications evaluated ImmunoCyt,<sup>31,46,48,50,54,74,78,79,81,82,85-88</sup> and 1 study evaluated CxBladder.<sup>52</sup> Sample sizes ranged from 26 to 3,916 and the proportion of patients with bladder cancer ranged from 3 to 81 percent. The focus of 8 studies in 9 publications was diagnostic testing for patients with signs or symptoms suggestive of bladder cancer for initial diagnosis, 16 studies focused on diagnostic testing for surveillance in patients previously treated for non-muscle-invasive bladder cancer (NMIBC), and 19 studies evaluated mixed populations. Forty-three studies in 44 publications were conducted in the United States or Europe<sup>30-37,39-51,53-55,57,59-68,70-73,75,83,87,89</sup> and 26 studies in 27 publications used a prospective design.<sup>30,35-38,41,42,44-47,50,52,54,56-62,64,66,68,69,71,89</sup> Two studies were rated low risk of bias,<sup>35,36</sup> 52 studies medium risk of bias,<sup>30-34,37-39,41-46,48-76,78-82,84-89</sup> and

three studies high risk of bias<sup>40,77,83</sup> (See Appendix F). Eleven studies reported blinded interpretation of the reference standard,<sup>30,35,36,38,44,45,54,57,62,71,73</sup> 12 studies reported enrollment of a random or consecutive sample of patients,<sup>30,31,35,36,38,43,46,50,52,54,55,59</sup> and 38 studies reported predefined criteria for a positive test.<sup>30-42,44-51,53-73,75,83,87,89</sup>

## Quantitative NMP22

Sensitivity of quantitative NMP22 was 0.69 (95% CI 0.62 to 0.75) and specificity was 0.77 (95% CI 0.70 to 0.83), based on 19 studies, for a positive likelihood ratio of 3.05 (95% CI 2.28 to 4.10) and negative likelihood ratio of 0.40 (95% CI 0.32 to 0.50) (Table 3; Figure 3).<sup>30,32,33,39,52,53,57,60,61,63,65-67,72,73,75,83,87,89</sup> All studies except for two<sup>33,52</sup> used a cutoff of >10 for a positive test. Excluding these two studies resulted in similar sensitivity (0.70, 95% CI 0.63 to 0.77) and specificity (0.77, 95% CI 0.69 to 0.83). Diagnostic accuracy was similar for evaluation of symptoms (sensitivity 0.67 [95% CI 0.55 to 0.77]; 9 studies and specificity 0.84 [95% CI 0.75 to 0.90]; 7 studies)<sup>30,33,52,53,60,61,67,73,89</sup> and for surveillance (sensitivity 0.61 [95% CI 0.49 to 0.71]; 10 studies and specificity 0.71 [95% CI 0.60 to 0.81]; 8 studies).<sup>30,33,63,65-67,72,75,83,89</sup> Excluding one study rated high risk of bias<sup>83</sup> and restricting the analysis to studies that used a prospective design, were conducted in the United States or Europe, or used a prespecified threshold to define a positive test, had little effect on pooled estimates and did not reduce statistical heterogeneity. Restricting the analysis to studies that reported blinded interpretation of the reference standard resulted in higher specificity, but the pooled estimate was only based on three studies (0.89, 95% CI 0.78 to 0.95).<sup>30,57,73</sup>

## Qualitative NMP22

Sensitivity of qualitative NMP22 was 0.58 (95% CI 0.39 to 0.75) and specificity was 0.88 (95% CI 0.78 to 0.94), based on four studies, for a positive likelihood ratio of 4.89 (95% CI 3.23 to 7.40) and negative likelihood ratio of 0.48 (95% CI 0.33 to 0.71) (Table 3; Figure 4).<sup>35,36,38,52</sup> Restricting the analysis to two studies that were rated low risk of bias resulted in similar estimates (sensitivity 0.53 [95% CI 0.29 to 0.75] and specificity 0.87 [95% CI 0.74 to 0.94]).<sup>35,36</sup> Two studies each reported diagnostic accuracy for evaluation of symptoms (sensitivity 0.47 [95% CI 0.33 to 0.61] and specificity 0.93 [95% CI 0.81 to 0.97])<sup>35,52</sup> and for surveillance (sensitivity 0.70 [95% CI 0.40 to 0.89] and specificity 0.83 [95% CI 0.75 to 0.89]),<sup>36,38</sup> resulting in imprecise estimates. Other subgroup and sensitivity analysis were also limited by the small numbers of studies.

## Qualitative BTA

Sensitivity of qualitative BTA was 0.64 (95% CI 0.58 to 0.69, 22 studies)<sup>32,33,39-42,44,45,49,51,56,58,60,64,67,68,70,77,80,83,87,89</sup> and specificity was 0.77 (95% CI 0.73 to 0.81, 21 studies),<sup>32,33,39,40,42,44,45,49,51,56,58,60,64,67,68,70,77,80,83,87,89</sup> for a positive likelihood ratio of 2.80 (95% CI 2.31 to 3.39) and negative likelihood ratio of 0.47 (95% CI 0.30 to 0.55) (Table 3; Figure 5). Excluding three studies rated high risk of bias<sup>40,77,83</sup> resulted in similar pooled estimates and did not reduce statistical heterogeneity. Sensitivity was higher for evaluation of symptoms (0.76, 95% CI 0.67 to 0.83; 8 studies)<sup>33,45,51,56,60,67,77,89</sup> than for surveillance (0.60, 95% CI 0.55 to 0.65; 11 studies),<sup>33,41,44,45,56,59,67,68,77,80,83,89</sup> but specificity was similar (0.78 [95% CI 0.66 to 0.87]; 6 studies and 0.76 [95% CI 0.69 to 0.83]; 8 studies, respectively. Restricting analyses to studies that used a prospective design, were conducted in the United States or Europe, or reported

interpretation of the reference standard blinded to BTA test results, had little effect on pooled estimates and did not reduce statistical heterogeneity.

## Quantitative BTA

Sensitivity of quantitative BTA was 0.65 (95% CI 0.54 to 0.75) and specificity was 0.74 (95% CI 0.64 to 0.82), based on four studies, for a positive likelihood ratio of 2.52 (95% CI 1.86 to 3.41) and negative likelihood ratio of 0.47 (95% CI 0.37 to 0.61) (Table 3; Figure 6).<sup>34,42,69,83</sup> Estimates were similar in three studies that used a threshold of >14 to define a positive test<sup>42,69,83</sup> and when one high risk of bias study<sup>83</sup> was excluded from the analysis. Only one study<sup>69</sup> reported diagnostic accuracy for evaluation of symptoms (sensitivity 0.76 [95% CI 0.61 to 0.87]; specificity 0.53 [95% CI 0.38 to 0.68]) and two studies<sup>69,83</sup> for surveillance (sensitivity 0.58 [95% CI 0.46 to 0.69]; specificity 0.79 [95% CI 0.72 to 0.85]).

## FISH

Sensitivity of FISH was 0.63 (95% CI 0.50 to 0.75) and specificity was 0.87 (95% CI 0.79 to 0.93), based on 11 studies, for a positive likelihood ratio of 5.02 (95% CI 2.93 to 8.60) and negative likelihood ratio of 0.42 (95% CI 0.30 to 0.59) (Table 3; Figure 7).<sup>37,40,43,55,62,71,75,76,84,85,87</sup> Estimates were similar when one high risk of bias study<sup>40</sup> was excluded, prostatitis or when the analysis was restricted to studies that used a prospective design or reported interpretation of the reference standard blinded to FISH results. For surveillance, sensitivity was 0.55 (95% CI 0.36 to 0.72; 7 studies) and specificity was 0.80- (95% CI 0.66 to 0.89; 6 studies).<sup>37,43,55,62,71,75,85</sup> For evaluation of symptoms, sensitivity of FISH was 0.73 (95% CI 0.50 to 0.88), based on two studies.<sup>55,84</sup> Only one study reported specificity of FISH for evaluation of symptoms (0.95, 95% CI 0.87 to 0.98)).<sup>84</sup>

## ImmunoCyt

Sensitivity of ImmunoCyt was 0.78 (95% CI 0.68 to 0.85) and specificity was 0.78 (95% CI 0.72 to 0.82), based on 14 studies, for a positive likelihood ratio of 3.49 (95% CI 2.82 to 4.32) and negative likelihood ratio of 0.29 (95% CI 0.20 to 0.41) (Table 3; Figure 8).<sup>31,46,48,50,74,75,78,79,81,82,85-88</sup> Excluding one high risk of bias study<sup>86</sup> or restricting the analysis to studies that used a prospective design had little effect on estimates. For evaluation of symptoms, sensitivity was 0.85 (95% CI 0.78 to 0.90; 6 studies) and specificity was 0.83 (95% CI 0.77 to 0.87; 7 studies),<sup>46,50,74,78,79,81,82</sup> and for surveillance, sensitivity was 0.75 (95% CI 0.64 to 0.83; 7 studies) and specificity was 0.76 (95% CI 0.70 to 0.81; 8 studies).<sup>46,48,50,75,78,79,85,88</sup>

## CxBladder

One study (rated medium risk of bias) of CxBladder reported a sensitivity of 0.82 (95% CI 0.70 to 0.90) and specificity of 0.85 (95% CI 0.81 to 0.88) for evaluation of symptoms, for a positive likelihood ratio of 5.53 (95% CI 4.28 to 7.15) and negative likelihood ratio of 0.21 (95% CI 0.13 to 0.36) (Table 3).<sup>52</sup>

## Head-to-Head Comparisons

Relatively few studies directly compared the diagnostic accuracy of different urinary biomarkers in the same population against cystoscopy and biopsy (Table 4). In seven studies, there were no differences between quantitative NMP22 (based on a cutoff of >10 U/mL) versus qualitative BTA in sensitivity (0.69, 95% CI 0.62 to 0.76 vs. 0.66, 95% CI 0.59 to 0.73, for a

difference of 0.03, 95% CI -0.04 to 0.10) or specificity (0.73, 95% CI 0.62 to 0.82 vs. 0.76, 95% CI 0.66 to 0.84, for a difference of 0.03, 95% CI -0.08 to 0.01).<sup>32,39,60,67,83,87,89</sup> Findings were similar when one high risk of bias study was excluded,<sup>83</sup> when the analysis was restricted to studies that used a prospective design,<sup>60,67,89</sup> or when analyses were stratified according to different tumor stages or grades.

Three studies found ImmunoCyt associated with higher sensitivity than FISH (0.71 [95% CI 0.54 to 0.84] vs. 0.61 [95% CI 0.43 to 0.76], for a difference of 0.11 [95% CI 0.001 to 0.21]) but lower specificity (0.71 [95% CI 0.62 to 0.79] vs. 0.79 [95% CI 0.71 to 0.85], for a difference of -0.08 [95% CI -0.15 to -0.001]).<sup>75,85,87</sup> ImmunoCyt was also associated with higher sensitivity than FISH for Ta, T1, and low grade numbers (differences in sensitivity ranged from 0.24 to 0.35).

Two studies found qualitative BTA associated with lower specificity than FISH (difference -0.16, 95% CI -0.24 to -0.08),<sup>40,87</sup> two studies found quantitative NMP22 associated with lower specificity than ImmunoCyt (difference -0.16, 95% CI -0.28 to -0.04),<sup>75,87</sup> and two studies found quantitative NMP22 associated with lower specificity than FISH (difference -0.18, 95% CI -0.28 to -0.08),<sup>75,87</sup> with no clear differences in sensitivity. Evidence for other head-to-head comparisons of urinary biomarkers was based on one or two studies with imprecise estimates and methodological shortcomings, precluding reliable conclusions regarding comparative test performance (Table 4).

Sixteen studies found sensitivity of various urinary biomarkers plus cytology associated with higher sensitivity than the urinary biomarker alone (0.81, 95% CI 0.75 to 0.86 vs. 0.69, 95% CI 0.61 to 0.76, for a difference of 0.13, 95% CI 0.08 to 0.17), with no difference in specificity (Table 4);<sup>31,34,36,38,45,48,50,53,55,69,77,79,85-88</sup> results were similar in a subgroup of eight studies of ImmunoCyt plus Cytology versus ImmunoCyt alone.<sup>31,48,50,79,85-88</sup> In studies that stratified analyses according to tumor stage and grade, there were no clear differences in sensitivity for Ta, T1, or low grade (G1, low grade, or low malignant potential).<sup>31,48,50,79,85-88</sup>

**Key Question 1a. Does the diagnostic accuracy differ according to patient characteristics (e.g., age, sex, race/ethnicity) or according to the nature of the presenting signs or symptoms?**

## Key Points

- Effects of tumor stage: Across urinary biomarkers, sensitivity increased with higher tumor stage. Evidence was most robust for quantitative NMP22 (11 studies), qualitative BTA (18 studies), and FISH (8 studies); the association between higher tumor stage and increased sensitivity was least pronounced for ImmunoCyt (10 studies). Sensitivity for CIS tumors was generally similar to or slight lower than for T1 tumors (SOE: high).
- Effects of tumor grade: Across urinary biomarkers, sensitivity increased with higher tumor grade. Evidence was most robust for quantitative NMP22 (12 studies), ImmunoCyt (10 studies), qualitative BTA (18 studies), and FISH (9 studies) (SOE: high).
- Effects of tumor size: Two studies found sensitivity was higher for larger (>1 cm or >2 cm) smaller tumors (SOE: low).

- Evidence on the effects of patient characteristics such as age, sex, smoking status, and presence of other clinical conditions on diagnostic accuracy of urinary biomarkers was limited, but did not clearly or consistently indicate effects on sensitivity or specificity (SOE: low).

## Detailed Synthesis

Across urinary biomarkers, sensitivity increased with higher tumor stage (Table 5). For quantitative NMP 22, sensitivity for Ta tumors was 0.48 (95% CI 0.36 to 0.60; 10 studies), for T1 tumors was 0.72 (95% CI 0.60 to 0.81; 11 studies), and for  $\geq$ T2 tumors was 0.82 (95% CI 0.70 to 0.89; 11 studies;  $p=0.002$  for overall difference between categories).<sup>30,32,33,39,52,60,61,83,87,89</sup> The difference in sensitivity between T1 and Ta tumors was 0.23 (95% CI 0.14 to 0.32) and between  $\geq$ T2 and T1 tumors was 0.10 (95% CI 0.01 to 0.20). For qualitative BTA, sensitivity for Ta tumors was 0.49 (95% CI 0.41 to 0.56; 18 studies), for T1 tumors was 0.74 (95% CI 0.66 to 0.80; 17 studies), and for  $\geq$ T2 tumors was 0.89 (95% CI 0.83 to 0.93; 17 studies;  $p<0.0001$  for overall difference between categories).<sup>32,33,39,40,42,44,45,49,56,58,60,62,64,70,77,83,87,89</sup> The difference in sensitivity between T1 and Ta tumors was 0.25 (95% CI 0.18 to 0.32) and between  $\geq$ T2 and T1 tumors was 0.15 (95% CI 0.08 to 0.22). A similar pattern was observed for FISH, based on eight studies (Table 4).<sup>40,55,62,71,76,84,85,87</sup> For quantitative NMP22, FISH, and qualitative BTA, sensitivity for CIS tumors was similar or slightly lower than for T1 tumors. For ImmunoCyt, the association between higher tumor stage and increased sensitivity was less clear. Sensitivity for Ta tumors was 0.74 (0.63 to 0.83) and for T1 and  $\geq$ T2 tumors was 0.81, based on 10 studies.<sup>31,46,48,50,81,82,85-87</sup>

Sensitivity also increased across urinary biomarkers with higher tumor grade (Table 5). For quantitative NMP22, sensitivity for G1 tumors was 0.44 (95% CI 0.32 to 0.57), for G2 tumors was 0.58 (95% CI 0.47 to 0.69), and for G3 tumors was 0.75 (95% CI 0.65 to 0.83), based on 12 studies ( $p<0.0001$  for difference between categories).<sup>30,32,33,39,52,60,61,63,75,83,87,89</sup> The difference in sensitivity between G2 and G1 tumors was 0.14 (95% CI 0.05 to 0.24) and between G3 and G2 tumors was 0.16 (95% CI 0.09 to 0.24). For qualitative BTA, sensitivity for G1 tumors was 0.39 (95% CI 0.30 to 0.48), for G2 tumors was 0.63 (95% CI 0.54 to 0.71), and for G3 tumors was 0.81 (95% CI 0.75 to 0.87), based on 19 studies ( $p<0.0001$  for difference between categories).<sup>32,33,39-42,44,45,49,56,58,60,62,64,70,77,83,87,89</sup> The difference in sensitivity between G2 and G1 tumors was 0.24 (95% CI 0.17 to 0.32) and between G3 and G2 tumors was 0.18 (95% CI 0.12 to 0.25). A similar pattern was observed for FISH, based on seven studies (Table 5).<sup>40,55,62,71,75,84,87</sup> For ImmunoCyt, sensitivity for low-grade (G1, low grade, or low malignant potential) tumors was 0.74 (95% CI 0.66 to 0.80) and for high-grade tumors (G2, G3, or high grade) was 0.83 (95% CI 0.78 to 0.88), for a difference of 0.10 (95% CI 0.03 to 0.17), based on 10 studies.<sup>46,48,50,75,79,81,82,85-87</sup>

Similar patterns for effects of tumor stage and grade were observed for other urinary biomarkers (Table 5). However, estimates were based on smaller numbers of studies and were less precise, and differences were not always statistically significant.

One study found higher sensitivity of qualitative BTA for tumors 2 to 5 cm (0.96) and  $>5$  cm (1.0) than for tumors  $<2$  cm (0.60, Fisher's exact  $p<0.0005$ )<sup>56</sup> and one study found higher sensitivity of FISH for tumors 1-3 cm (0.93) or  $>3$  cm (0.94) than for tumors  $<1$  cm (0.46, Fisher's exact  $p=0.001$ ).<sup>55</sup>

Few studies evaluated effects of patient characteristics on diagnostic accuracy of urinary biomarkers. One study found quantitative and qualitative NMP22 and CxBladder each associated

with higher sensitivity for multifocal versus unifocal tumors, though differences were not statistically significant.<sup>52</sup> There were no clear differences in diagnostic accuracy according to sex, age, or smoking status.<sup>35,52,58</sup> Three studies<sup>74,81,82</sup> of ImmunoCyt that specifically enrolled patients with microscopic or macroscopic hematuria reported sensitivity and specificity that was similar to the overall estimates from studies of patients with signs or symptoms of bladder cancer. One study of quantitative NMP22 did not find a difference in sensitivity between patients who had received prior intravesical therapy and those who had not.<sup>65</sup>

Eight studies of various urinary biomarkers did not find consistent differences in specificity according to factors such as presence of other urological cancers, renal calculi, prostatitis, benign prostatic hypertrophy, urinary tract infection, or hematuria, though specificity was higher when other urological conditions were not present in some studies.<sup>50,52,67,69,77,81,82,89</sup>

**Key Question 2.** For patients with non–muscle-invasive bladder cancer, does the use of a formal risk-adapted assessment approach to treatment decisions (e.g., based on Guidelines of the European Association of Urology or on urinary biomarker tests) decrease mortality or improve other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with treatment not guided by a formal assessed risk-adapted approach?

## Key Points

- No study compared clinical outcomes associated with use of a formal risk-adapted approach to guide treatment of NMIBC versus treatment not guided by a risk-adapted approach (SOE: insufficient).

## Detailed Synthesis

Though scoring systems to predict the risk of bladder cancer recurrence and disease progression are available and have undergone some validation,<sup>90-94</sup> no study compared clinical outcomes associated with use of a formal risk-adapted approach to guide treatment of NMIBC versus treatment not guided by a risk-adapted approach.

**Key Question 3.** For patients with non–muscle-invasive bladder cancer treated with transurethral resection of bladder tumor, what is the effectiveness of various intravesical chemotherapeutic or immunotherapeutic agents for decreasing mortality or improving other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with TURBT alone?

## Key Points

### BCG

- BCG was associated with decreased risk of bladder cancer recurrence (3 trials, RR 0.56, 95% CI 0.43 to 0.71,  $I^2=0\%$ ) and progression (4 trials, RR 0.39, 95% CI 0.24 to 0.64,

$I^2=40\%$ ) versus no intravesical therapy. No trial evaluated effects of BCG versus no intravesical therapy on risk of all cause mortality. One trial found BCG associated with decreased risk of bladder cancer mortality, but the difference was not statistically significant (RR 0.62, 95% CI 0.32 to 1.19). (SOE: insufficient for all-cause and bladder cancer mortality; SOE: low for recurrence and progression).

## **MMC**

- Mitomycin C (MMC) was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (8 trials, RR 0.71, 95% CI 0.57 to 0.89,  $I^2=72\%$ ), but there was no difference in risk of all cause-mortality (1 trial, HR 1.17, 95% CI 0.89 to 1.53) and effects on bladder cancer-specific mortality (1 trial, HR 0.71, 95% CI 0.34 to 1.46) and bladder cancer progression (5 trials, RR 0.68, 95% CI 0.39 to 1.20,  $I^2=0\%$ ) were not statistically significant (SOE: moderate for recurrence, low for progression, all-cause mortality, and bladder cancer-specific mortality).

## **Doxorubicin**

- Doxorubicin was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (10 trials, RR 0.80, 95% CI 0.72 to 0.88,  $I^2=46\%$ ), no difference in risk of bladder cancer progression (5 trials, RR 1.03, 95% CI 0.72 to 1.46,  $I^2=0\%$ ), and no clear effects on all-cause mortality (2 trials) or bladder cancer specific mortality (1 trial) (SOE: moderate for recurrence, low for progression, all-cause mortality, and bladder-cancer specific mortality).

## **Epirubicin**

- Epirubicin was associated with decreased risk of bladder cancer recurrence (9 trials, RR 0.63, 95% CI 0.53 to 0.75,  $I^2=64\%$ ) (SOE: moderate) but the effect on bladder cancer progression was not statistically significant (8 trials, RR 0.79, 95% CI 0.84 to 1.30,  $I^2=27\%$ ) (SOE: low).

## **Gemcitabine**

- One trial found no difference between single instillation gemcitabine versus no intravesical therapy in risk of bladder cancer recurrence (RR 0.98, 95% CI 0.70 to 1.36); estimates for progression (RR 3.00, 95% CI 0.32 to 28.4), all-cause mortality (RR 0.50, 95% CI 0.13 to 2.00), and bladder cancer-specific mortality were very imprecise (RR 1.00, 95% CI 0.06 to 15.81) (SOE: low for bladder cancer recurrence; SOE: insufficient for all-cause and bladder cancer mortality and progression).

## **Interferon Alpha**

- Interferon alpha was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy that was not statistically significant (3 trials, RR 0.75, 95% CI 0.53 to 1.06,  $I^2=50\%$ ), decreased risk of bladder cancer progression (2 trials, RR 0.33, 95% CI 0.14 to 0.76,  $I^2=0\%$ ), and no difference in risk of bladder cancer specific mortality (1 trial, RR 1.00, 95% CI 0.15 to 6.75) (SOE: low).

## Interferon Gamma

- Interferon-gamma was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (1 trial, RR 0.72, 95% CI 0.51 to 1.01), with no difference in risk of bladder cancer progression (1 trial, RR 1.08, 95% CI 0.07 to 16.4) (SOE: low).

## Thiotepa

- Thiotepa was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy that was not statistically significant (5 trials, RR 0.78, 95% CI 0.58 to 1.06,  $I^2=69\%$ ), with insufficient evidence to determine effects on progression or mortality (SOE: low for recurrence, insufficient for all-cause and bladder cancer mortality and progression).

## Detailed Synthesis

Thirty-seven trials (reported in 46 publications) evaluated intravesical therapy plus TURBT versus TURBT without intravesical therapy (Tables 6, 7, 8, 9, 10, 11, 12; Appendixes E2, F2).<sup>95-140</sup> Five trials evaluated BCG,<sup>102-111</sup> seven trials MMC,<sup>111-118</sup> nine trials doxorubicin,<sup>112,113,115,116,119-125</sup> 10 trials epirubicin,<sup>103,119,126-134</sup> 3 trials interferon alpha,<sup>132,133,137,141</sup> one trial interferon-gamma,<sup>138</sup> two trials thiotepa,<sup>139,140</sup> and one trial gemcitabine.<sup>135</sup> Samples sizes ranged from 24 to 553 and duration of followup from a median of 9 months to 10.7 years. Mean age ranged from 52.1 to 71 years and the proportion of patients who were male ranged from 62.9 to 98 percent. Eight trials excluded patients with G3 tumors and 15 trials excluded patients with CIS lesions. In the other trials, the proportion with G3 tumors ranged from 0 to 43 percent and the proportion with CIS lesions ranged from 0 to 88 percent. Seven trials focused on patients with primary tumors and 11 trials focused on patients with recurrent tumors. One trial was rated high risk of bias,<sup>105,110</sup> and 35 trials medium risk of bias (Appendix F2).<sup>102-104,106-109,111-140</sup> Two trials reported blinding of outcomes assessors;<sup>127,132,133</sup> no trial blinded care provider or patients. Other methodological limitations included inadequate description of randomization and allocation concealment, and high attrition or failure to report attrition. Results are summarized in Table 15.

## BCG

Five trials (reported in 10 publications) randomized patients to BCG versus no intravesical therapy following TURBT (Table 6; Appendixes E2, F2).<sup>102-111</sup> The dose of BCG ranged from 75 mg to 150 mg. All trials evaluated maintenance therapy with BCG, except for one trial that was limited to 6-week induction therapy.<sup>106</sup>

No trial evaluated effects of BCG versus no intravesical therapy on risk of all cause mortality. One trial found BCG associated with decreased risk of bladder cancer mortality, but the difference was not statistically significant (RR 0.62, 95% CI 0.32 to 1.19).<sup>102</sup> BCG was associated with reduced risk of bladder cancer recurrence (3 trials, 29% vs. 50%, RR 0.56, 95% CI 0.43 to 0.71,  $I^2=0\%$ ) (Figure 9)<sup>103,104,111</sup> and progression (4 trials, 15% vs. 42%, RR 0.39, 95% CI 0.24 to 0.64,  $I^2=40\%$ ) (Figure 10).<sup>103-106</sup> One trial found BCG associated with a trend towards decreased risk of cystectomy versus no intravesical therapy, but the difference was not statistically significant (RR 0.61, 95% CI 0.33 to 1.14).<sup>106</sup>

All BCG trials that reported recurrence evaluated maintenance regimens. Statistical heterogeneity was present in the analysis of progression. Excluding one trial<sup>106</sup> that evaluated an induction regimen (also the only trial to focus on treatment of recurrent cancer, RR 0.56, 95% CI

0.42 to 0.75) eliminated statistical heterogeneity, but resulted in a similar estimate (RR 0.27, 95% CI 0.15 to 0.48,  $I^2=0\%$ ).

## MMC

Nine trials (reported in 10 publications) evaluated MMC versus no intravesical therapy<sup>97,101,111-118</sup> (Tables 7, 8; Appendixes E2, F2). The doses of MMC ranged from 5 mg to 40 mg. The number of instillations varied from one to 58: three trials evaluated a single instillation,<sup>114,117,118</sup> two trials evaluated an induction regimen (8 instillations over 4 or 8 weeks),<sup>97,112,116</sup> and 4 trials evaluated maintenance regimens (ranging from 5 instillations over 1 year to 38 instillations over 2 years).<sup>101,111-113,115,118</sup> Duration of followup ranged from a mean of 35 months to a median of 94 months.

One trial found no difference between MMC administered as a single dose or as a maintenance regimen (5 instillations every 1 year) versus no intravesical therapy in risk of all cause-mortality (HR 1.17, 95% CI 0.89 to 1.53) or bladder cancer-specific mortality (HR 0.71, 95% CI 0.34 to 1.46).<sup>118</sup>

MMC was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (8 trials, RR 0.71, 95% CI 0.57 to 0.89,  $I^2=72\%$ ) (Figure 11).<sup>97,101,111,112,114-117</sup> Results were very similar using the profile likelihood method (RR 0.71, 95% CI 0.52 to 0.91). Results favored MMC in all trials, including two trials of single dose therapy (RR 0.43, 95% CI 0.14 to 1.31),<sup>114,117</sup> as well as in other stratified and sensitivity analyses. Restricting the analysis to trials of multiple MMC instillations gave results similar to the overall pooled estimate (6 trials, RR 0.80 95% CI 0.67 to 0.95,  $I^2=50\%$ ).<sup>97,101,111,112,115,116</sup> Findings were also consistent in a ninth trial that could not be pooled, which found MMC associated with greater recurrence-free survival over two years (log-rank test,  $p=0.01$ ) and lower annual recurrence rate over two years (42% vs. 82%,  $p=0.001$ ).<sup>118</sup>

MMC was associated with lower risk than no intravesical therapy of bladder cancer progression, but the difference was not statistically significant (5 trials, RR 0.68, 95% CI 0.39 to 1.20,  $I^2=0\%$ ) (Figure 12).<sup>97,113-115,117</sup> Excluding two trials of single dose therapy resulted in a similar estimate (3 trials, RR 0.67, 95% CI 0.38 to 1.20,  $I^2=0\%$ ).<sup>114,117</sup> One trial that did not provide poolable data also reported no statistically significant difference in risk of progression with either single dose or maintenance MMC.<sup>118</sup>

## Doxorubicin

Eleven trials (reported in 13 publications) evaluated doxorubicin versus no intravesical therapy<sup>95,101,112,113,115,116,119-125</sup> (Tables 9, 10; Appendixes E2, F2). The doses of doxorubicin ranged from 10 mg to 80 mg; the most commonly studied doses were 20 mg, 30 mg, and 50 mg. The number of instillations varied from 1 to 58: 2 trials used a single instillation,<sup>95,125</sup> 1 trial used an induction regimen (8 instillations over 4 weeks),<sup>112,116</sup> and 1 trial used a regimen of 6 instillations in the 2 weeks prior to TURBT.<sup>123</sup> The remaining trials used maintenance regimens (ranging from 15 instillations over 1 year to 58 instillations over 2 years). Duration of followup for recurrence ranged from 6 months to a median of 5 years, with followup as long as 10.9 years for mortality.

Two trials found no clear differences between maintenance regimens of doxorubicin versus no intravesical therapy in risk of all-cause or bladder cancer-specific mortality after 10 years of followup. In one trial, doxorubicin was associated with increased risk of all-cause mortality (30% vs. 17%, RR 1.83, 95% CI 0.78 to 4.28) and disease-specific mortality (6.5% vs. 2.8%, RR

2.35, 95% CI 0.25 to 21.6), but estimates were imprecise and the differences were not statistically significant.<sup>120</sup> A second trial found no differences between doxorubicin versus no intravesical therapy in all-cause mortality (54% vs. 58%; RR 0.93, 95% CI 0.73 to 1.18) or deaths due to bladder or other primary cancers (18% vs. 18%; RR 0.97, 95% CI 0.54 to 1.76).<sup>121</sup>

Doxorubicin was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (10 trials, RR 0.80, 95% CI 0.72 to 0.88,  $I^2=46\%$ ) (Figure 13).<sup>95,101,112,115,116,119-121,123,124</sup> Results were similar using the profile likelihood method. Findings were also similar in sensitivity and stratified analyses. The only trial that found no difference in risk of recurrence used doses of doxorubicin (10 to 80 mg) that varied depending on the patient's bladder capacity (RR 0.94, 95% CI 0.79 to 1.13).<sup>115</sup> Excluding one trial of single instillation therapy (RR 0.89, 95% CI 0.63 to 1.01)<sup>95</sup> had no effect on the pooled estimate and did not reduce heterogeneity (9 trials, RR 0.79, 95% CI 0.71 to 0.87,  $I^2=49\%$ ). One trial that did not provide poolable data also found a single instillation with doxorubicin associated with improved recurrence-free survival at a median followup of 41 months (log-rank test,  $p=0.0026$ ).<sup>125</sup>

There was no difference between doxorubicin versus no intravesical therapy in risk of bladder cancer progression (5 trials, RR 1.03, 95% CI 0.72 to 1.46,  $I^2=0.0\%$ ).<sup>113,115,119,120,122</sup> Findings were similar in sensitivity and subgroup analyses.

## Epirubicin

Ten trials (reported in 11 publications) evaluated epirubicin versus no intravesical therapy (Tables 11, 12; Appendixes E2, F2).<sup>103,119,126-134</sup> The doses of epirubicin ranged from 20 mg to 100 mg, with 50 mg and 80 mg the most commonly studied dosages. The number of instillations varied from 1 to 24: 5 trials used a single instillation,<sup>126-128,131,132</sup> 1 trial evaluated 2 instillations over 2 days,<sup>134</sup> 2 trials used an induction regimen (6 instillations over 6 weeks) followed by up to 7 additional maintenance doses over 2 years for recurrence-free patients,<sup>103,130</sup> and 3 trials used maintenance regimens (ranging from 18 instillations over 1 year to 24 instillations over 2 years).<sup>119,126,129</sup> Duration of followup ranged from a median of 20 months to 72 months.

Epirubicin was associated with reduced risk of bladder cancer recurrence versus no intravesical therapy (9 trials, RR 0.63, 95% CI 0.53 to 0.75,  $I^2=64\%$ ) (Figure 14).<sup>103,119,126-132</sup> Findings were similar in sensitivity and stratified analyses. One trial which didn't report poolable data for recurrence reported longer median recurrence-free survival for epirubicin, 50 mg (2 instillations) compared with no adjuvant therapy (38 months vs. 13 months, log-rank test,  $p=0.05$ ).<sup>134</sup>

Epirubicin was also associated with reduced risk of bladder cancer progression versus no intravesical therapy, but the difference was not statistically significant (8 trials, RR 0.79, 95% CI 0.48 to 1.30,  $I^2=27\%$ ) (Figure 15).<sup>103,119,126,127,129-131,134</sup> In stratified analyses, there was no clear pattern to suggest that longer duration of therapy was associated with decreased risk of progression. An outlier trial found a maintenance regimen of epirubicin 20 mg (24 instillations over 2 years) associated with an increased risk in progression (21% [9/43] vs. 3% [1/32]; RR 6.70, 95% CI 0.89 to 50.22), though the difference was not statistically significant and the estimate was very imprecise.<sup>129</sup>

No trial evaluated effects of intravesical epirubicin on overall or bladder cancer-specific mortality.

## Gemcitabine

One trial (n=248) evaluated a single instillation of gemcitabine versus placebo (Tables 13, 14; Appendixes E2, F2).<sup>135</sup> It found no difference between gemcitabine and placebo in risk of bladder cancer recurrence after 24 months (RR 0.98, 95% CI 0.70 to 1.36). Estimates for progression (RR 3.00, 95% CI 0.32 to 28.4), all-cause mortality (2.4% vs. 4.8%, RR 0.50, 95% CI 0.13 to 2.00), and bladder cancer-mortality (0.8% vs. 0.8%, RR 1.00, 95% CI 0.06 to 15.81) were very imprecise.

## Interferon Alpha

Three trials (reported in 4 publications) evaluated interferon alpha versus no intravesical therapy (Tables 13, 14; Appendixes E2, F2).<sup>132,133,136,137</sup> The doses of interferon alpha ranged from 40 million units (MU) to 80 MU. One trial evaluated a single instillation<sup>132,133</sup> and two trials evaluated maintenance regimens (21 or 22 instillations over 1 year).<sup>136,137</sup> Duration of followup ranged from 2 years to a median of 72 months.

One trial found no difference between interferon alpha and placebo in risk of overall and bladder cancer-specific mortality (5% [2/39] vs. 5% [2/39], RR 1.00, 95% CI 0.15 to 6.75).<sup>137</sup>

Interferon alpha was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy, but the difference was not statistically significant (3 trials, RR 0.75, 95% CI 0.53 to 1.06,  $I^2=50\%$ ) (Figure 16).<sup>132,136,137</sup> Results were similar using the profile likelihood method. One trial found interferon alpha associated with decreased risk<sup>136</sup> and two trials no effect.<sup>132,137</sup> The trial that found interferon alpha associated with decreased risk of bladder cancer evaluated interferon alpha using doses of 40, 60, and 80 MU; only the 80 MU dose was associated with decreased risk of recurrence (RR 0.35, 95% CI 0.14 to 0.89).<sup>136</sup> The other two trials evaluated doses of 60 MU or less and one<sup>132,133</sup> evaluated single instillation therapy.

Interferon alpha was associated with lower risk of bladder cancer progression versus no intravesical therapy (2 trials, RR 0.33, 95% CI 0.14 to 0.76,  $I^2=0.0\%$ ) (Figure 17).<sup>136,137</sup>

## Interferon Gamma

One trial (n=54) found induction therapy (8 instillations over 8 weeks) with interferon-gamma 21 MU (8 instillations over 8 weeks) patients with recurrent and/or multiple TaG2, TaG3, or T1/G2-G3 tumors associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (62% vs. 86%, RR 0.72, 95% CI 0.51 to 1.01) (Tables 13, 14; Appendixes E2, F2).<sup>138</sup> There was no difference in risk of bladder cancer progression (3.8% vs. 3.6%, RR 1.08, 95% CI 0.07 to 16.4) after a median followup of 9 months, but the estimate was imprecise. The trial did not report mortality.

## Thiotepa

Five trials (reported in 6 publications) evaluated thiotepa versus no intravesical therapy (Tables 13, 14; Appendixes E2, F2).<sup>96,98-100,139,140</sup> The doses of thiotepa ranged from 30 mg to 90 mg, with the most commonly studied dose 30 mg. The number of instillations varied from 1 to 32: 2 trials used a single instillation<sup>96,98,99</sup> and 4 trials used maintenance regimens (ranging from 5 instillations over 1 year to 32 instillations over 2 years).<sup>98-100,139,140</sup> Duration of followup ranged from a mean of 14.9 months to a median of 8.75 years.

One trial found no difference between thiotepa 30 mg five instillations or single dose versus no intravesical therapy in risk of all-cause mortality (HR 0.99, 95% CI 0.56 to 1.82); estimates for bladder cancer-specific mortality favored no intravesical therapy, but were imprecise (HR

1.61 [95% CI 0.59 to 4.39] and HR 1.73 [95% CI 0.65 to 4.63] for multi-instillation and single dose regimens, respectively).<sup>98,99</sup> Estimates for the combined outcome of bladder cancer progression or bladder cancer mortality were similar, but results were not reported separately for bladder cancer progression alone.

Thiotepa was associated with decreased risk of bladder cancer recurrence versus no intravesical therapy, but the difference was not statistically significant (5 trials, RR 0.78, 95% CI 0.58 to 1.06,  $I^2=69\%$ ) (Figure 18).<sup>96,98,100,139,140</sup> Results were similar using the profile likelihood method. Estimates from trials that evaluated a single instillation (2 trials, RR 0.83, 95% CI 0.44 to 1.56,  $I^2=83\%$ )<sup>96,98</sup> and multiple instillations (4 trials, RR 0.74, 95% CI 0.49 to 1.12,  $I^2=70\%$ )<sup>99,100,139,140</sup> were similar. Stratification according to duration of followup eliminated statistical heterogeneity. Trials with followup greater than 1 year found thiotepa associated with decreased risk of recurrence (3 trials that evaluated 4 regimens, RR 0.55, 95% CI 0.42 to 0.73,  $I^2=0\%$ ),<sup>96,139,140</sup> but there was no difference in trials that evaluated regimens at 1 year or less (2 trials that evaluated 3 regimens, RR 1.10, 95% CI 0.90 to 1.34,  $I^2=0\%$ ).<sup>98,100</sup> Other sensitivity and stratified analyses had no effect on pooled estimates.

There was no difference in risk of bladder cancer progression of stage (4.0% vs. 5.8%, RR 0.69, 95% CI 0.16 to 2.97), grade (6.7% vs. 7.2%, RR 0.92, 95% CI 0.28 to 3.04), or both stage and grade (2.7% vs. 2.9%, RR 0.92, 95% CI 0.13 to 6.36) in one study.<sup>100</sup>

**Key Question 3a. What is the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents, as monotherapy or in combination?**

## Key Points

### BCG Versus MMC

- There were no differences between BCG versus MMC in risk of bladder cancer recurrence overall (10 trials, RR 0.95, 95% CI 0.81 to 1.11,  $I^2=67\%$ ), but BCG was associated with decreased risk in the subgroup of trials that evaluated maintenance regimens (5 trials, RR 0.79, 95% CI 0.71 to 0.87,  $I^2=0\%$ ). There was no difference in risk of all-cause (7 trials, RR 0.94, 95% CI 0.83 to 1.06,  $I^2=0\%$ ) or bladder cancer-specific mortality (5 trials, RR 0.77, 95% CI 0.54 to 1.10,  $I^2=0\%$ ), or progression (7 trials, RR 0.88, 95% CI 0.66 to 1.17,  $I^2=18\%$ ) (SOE: moderate for all-cause mortality, bladder cancer-specific mortality, and progression; low for recurrence).
- There were no differences between BCG versus BCG plus MMC given sequentially in risk of all-cause (1 trial, RR 1.57, 95% CI 0.67 to 3.71) or bladder cancer-specific

mortality (2 trials, RR 1.10, 95% CI 0.50 to 2.38,  $I^2=17\%$ ), bladder cancer recurrence (4 trials, RR 1.03, 95% CI 0.70 to 1.52,  $I^2=75\%$ ), progression (3 trials, RR 0.87, 95% CI 0.40 to 1.91,  $I^2=22\%$ ), or cystectomy (4 trials, RR 0.87, 95% CI 0.41 to 1.84,  $I^2=0\%$ ) (SOE: low for mortality, recurrence, progression, and cystectomy).

- There were no differences between BCG plus MMC administered sequentially versus MMC in risk of all-cause (2 trials, RR 1.53, 95% CI 0.72 to 1.74 and RR 0.95, 95% CI 0.71 to 1.30) or bladder cancer mortality (2 trials, RR 0.64, 95% CI 0.22 to 1.88 and RR 0.95, 95% CI 0.45 to 1.56), bladder cancer recurrence (2 trials, RR 0.88, 95% CI 0.75 to 1.03,  $I^2=0\%$ ), or progression (2 trials, RR 0.82 [95% CI 0.40 to 1.68] and RR 1.28 [95% CI 0.35 to 4.61]) (SOE: low).

## BCG Versus Doxorubicin

- BCG was associated with decreased risk of bladder cancer recurrence versus doxorubicin (2 trials [RR 0.31, 95% CI 0.16 to 0.61] and RR 0.75 [95% CI 0.64 to 0.88]), but there were no differences in risk of all-cause mortality (2 trials, RR 0.40 [95% CI 0.01 to 12] and RR 1.00 [95% CI 0.71 to 1.37]), bladder cancer progression (1 trial, RR 0.20, 95% CI 0.02 to 1.72) (SOE: low for mortality, recurrence progression, and cystectomy).

## BCG Versus Epirubicin

- BCG was associated with reduced risk of bladder cancer recurrence versus epirubicin, but statistical heterogeneity was high (5 trials, RR 0.54, 95% CI 0.40 to 0.74,  $I^2=76\%$ ). Estimates favored BCG for all-cause (3 trials, RR 0.72, 95% CI 0.44 to 1.19,  $I^2=87\%$ ) and bladder cancer-specific mortality (3 trials, RR 0.72, 95% CI 0.25 to 2.08,  $I^2=80\%$ ), and bladder cancer progression (5 trials, RR 0.60, 95% CI 0.36 to 1.01,  $I^2=47\%$ ), but differences were not statistically significant (SOE: moderate for recurrence, low for all-cause mortality, bladder cancer-specific mortality, and progression).
- There was no difference between BCG versus BCG plus epirubicin administered sequentially in risk of bladder cancer recurrence (3 trials, RR 1.25, 95% CI 0.92 to 1.69,  $I^2=0\%$ ). BCG was associated with increased risk of bladder cancer progression (3 trials, RR 1.92, 95% CI 0.73 to 5.07,  $I^2=0\%$ ), but the difference was not statistically significant (SOE: low).
- One trial found no differences between BCG versus epirubicin plus interferon alpha-2b in risk of bladder cancer mortality (RR 0.79, 95% CI 0.32 to 1.63) or progression-free survival, though BCG was associated with decreased risk of bladder cancer recurrence (RR 0.66, 95% CI 0.51 to 0.85) (SOE: low).

## BCG Versus Gemcitabine

- There were no differences between BCG versus gemcitabine in risk of all-cause mortality (1 trial, RR 1.20, 95% CI 0.04 to 34), progression (2 trials, RR 1.11 [95% CI 0.53 to 2.34] and RR 0.52 [95% CI 0.13 to 2.06]) or quality of life (1 trial) (SOE: low for mortality, quality of life, and progression).
- Evidence from three trials was insufficient to determine effects of BCG versus gemcitabine on risk of bladder recurrence, due to clinical heterogeneity and inconsistent findings (RR 1.67 [95% CI 1.21 to 2.29], RR 0.53 [95% CI 0.28 to 1.01], and RR 0.76 [95% CI 0.44 to 1.90]) (SOE: insufficient).

- There were no differences between BCG versus BCG plus gemcitabine administered sequentially in risk of bladder cancer recurrence (1 trial, RR 0.86, 95% CI 0.49 to 1.51) or progression (1 trial, RR 1.18, 95% CI 0.30 to 4.61) (SOE: low for progression and recurrence).

## **BCG Versus Interferon**

- BCG was associated with reduced risk of bladder cancer recurrence versus interferon alpha-2a (1 trial, RR 0.57, 95% CI 0.39 to 0.82) but the difference in risk of bladder cancer progression was not statistically significant (1 trial, RR 0.69, 95% CI 0.25 to 1.92) (SOE: low for recurrence, and progression).
- In patients pretreated with MMC, BCG was associated with reduced risk of bladder cancer recurrence versus alternating BCG plus interferon alpha-2b (1 trial, RR 0.42, 95% CI 0.30 to 0.59) (SOE: low).
- Differences between BCG versus coadministration of BCG and interferon alpha-2b in risk of bladder cancer recurrence (1 trial, RR 0.88, 95% CI .71 to 1.08) or progression (1 trial, RR 0.76, 95% CI 0.17 to 3.30) did not reach statistical significance (SOE: low for recurrence and progression).

## **BCG Versus Thiotepa**

- Two trials found maintenance therapy with BCG associated with decreased risk of recurrence versus thiotepa (RR 0.38 [95% CI 0.19 to 0.76] and RR 0.04 [95% CI 0.00 to 0.63]), but estimates for other outcomes were too imprecise to evaluate effects (SOE: low for recurrence, insufficient for progression, death, and cystectomy).

## **MMC Versus Doxorubicin**

- There was no difference between MMC versus doxorubicin in risk of bladder cancer recurrence (6 trials, RR 1.00, 95% CI 0.82 to 1.22,  $I^2=44\%$ ), but MMC was associated with a nonstatistically significant trends towards decreased risk of bladder cancer progression (4 trials, RR 0.63, 95% CI 0.37 to 1.08,  $I^2=21\%$ ) (SOE: low).

## **MMC Versus Epirubicin**

- There was no difference between MMC versus epirubicin in risk of bladder cancer recurrence in one trial (RR 1.16, 95% CI 0.52 to 2.58) (SOE: low).

## **MMC Versus Gemcitabine**

- In one trial, MMC was associated with no difference in risk of bladder cancer progression ( $p=0.29$ ). MMC was associated with increased risk of recurrence but the difference was not statistically significant (RR 1.64, 95% CI 0.64 to 4.19) (SOE: low).

## **MMC Versus Interferon Alpha**

- One trial found no difference between MMC versus interferon alpha in risk of bladder cancer recurrence (RR 0.77, 95% CI 0.58 to 1.01) or bladder cancer progression (RR 1.38, 95% CI 0.49 to 3.88) (SOE: low).

## MMC Versus Interferon Gamma

- MMC was associated with increased risk of bladder cancer recurrence versus interferon-gamma in one trial (RR 1.61, 95% CI 0.97 to 2.67) (SOE: low).

## MMC Versus Thiotepa

- Two trials found no difference between MMC versus thiotepa in risk of recurrence (RR 1.76 [95% CI 0.36 to 8.70] and RR 1.14 [95% CI 0.60 to 2.16]) (SOE: low).

## Doxorubicin Versus Epirubicin

- Doxorubicin was associated with increased risk of bladder cancer recurrence versus epirubicin (3 trials, RR 1.56, 95% CI 1.08 to 2.22,  $I^2=0\%$ ); the difference in risk of progression was not statistically significant (1 trial, RR 1.32, 95% CI 0.50 to 3.47) (SOE: low for recurrence and progression).

## Doxorubicin Versus Thiotepa

- There was no statistically significant difference between doxorubicin versus thiotepa in risk of bladder cancer recurrence (RR 1.22, 95% CI 0.76 to 1.94). Estimates from one trial for progression (RR 2.11, 95% CI 0.40 to 11.06), noncancer mortality (RR 0.35, 95% CI 0.01 to 8.45), and cancer-specific mortality (RR 3.17, 95% CI 0.13 to 76.1) were very imprecise (SOE: low for recurrence; SOE: insufficient for progression, noncancer mortality, and cancer-specific mortality).

## Epirubicin Versus Interferon Alpha

- Epirubicin was associated with decreased risk of bladder cancer recurrence versus interferon alpha in one trial (RR 0.67, 95% CI 0.49 to 0.91) (SOE: low).

## Detailed Synthesis

Fifty-four trials (reported in 66 publications) compared effects of intravesical therapy using one drug versus another (Tables 6, 7, 8, 9, 10, 11, 12; Appendixes E3, F2).<sup>101,103,111-113,115,116,119,132,133,141-196</sup> Fourteen trials evaluated BCG versus MMC,<sup>111,147-165</sup> two trials BCG and MMC versus MMC,<sup>166-169</sup> four trials BCG versus doxorubicin,<sup>170-172</sup> nine trials BCG versus epirubicin,<sup>103,173-181</sup> one trial BCG versus epirubicin plus interferon,<sup>182,183</sup> four trials BCG versus gemcitabine,<sup>184-187</sup> three trials BCG versus interferon alpha,<sup>188-190</sup> and one trial BCG versus thiotepa.<sup>172</sup> The comparison drugs were administered alone or as part of sequential therapy with BCG. Thirteen trials (reported in 15 publications) evaluated comparisons of intravesical therapies that did not involve BCG.<sup>112,113,115,116,119,132,133,141,191-196</sup> Four trials evaluated MMC versus doxorubicin,<sup>112,113,115,116,191</sup> one trial MMC versus epirubicin,<sup>192</sup> one trial MMC versus interferon alpha,<sup>193</sup> one trial MMC versus interferon-gamma,<sup>141</sup> one trial MMC versus gemcitabine,<sup>194</sup> three trials doxorubicin versus epirubicin,<sup>119,195,196</sup> one trial doxorubicin versus thiotepa,<sup>172</sup> and one trial epirubicin versus interferon alpha.<sup>132,133</sup>

Samples sizes ranged from 41 to 957 and duration of followup from 15 months to 9 years. Mean age ranged from 52.1 to 74 years and the proportion of patients who were male ranged from 55 to 97 percent. Five trials excluded patients with G3 tumors and 7 trials excluded patients with CIS lesions. In the other trials, the proportion with G3 tumors ranged from 0 to 73 percent and the proportion with CIS lesions ranged from 0 to 100 percent. Thirty-four trials focused on

patients with primary tumors and 29 trials focused on patients with recurrent tumors. Two trials were rated high risk of bias,<sup>186,196</sup> 41 trials medium risk of bias,<sup>103,111-113,115,116,119,132,133,141,147-154,156-169,171-181,183,185,187-195</sup> and 4 trials low risk of bias (Appendix F2).<sup>155,170,182,184</sup> Two trials reported blinding of outcomes assessors,<sup>133,158</sup> no trial blinded care provider or patients. Other methodological limitations included inadequate description of randomization and allocation concealment and high attrition or failure to report attrition. Results are summarized in Table 16.

## BCG Versus MMC

Ten trials (reported in 16 publications) randomized patients to BCG versus MMC<sup>111,147-161</sup> and four trials randomized patients to BCG versus BCG plus MMC given sequentially (Table 6; Appendixes E3, F2).<sup>162-165</sup> The dose of BCG ranged from 13.5 mg to 120 mg and the dose of MMC from 20 mg to 40 mg with the number of instillations ranging from 6 weekly instillations<sup>148,154</sup> to 42 weekly instillations administered over 3 years.<sup>154</sup> No trial compared single instillation therapy with BCG versus MMC and no trial of MMC utilized an “optimized” regimen.<sup>197,198</sup>

There was no difference between BCG versus MMC in risk of bladder cancer recurrence (10 trials, RR 0.95, 95% CI 0.81 to 1.11,  $I^2=677\%$ ) (Figure 19).<sup>111,147,151,153-156,159,158,161</sup> However, statistical heterogeneity was present. Stratification of trials according to whether they evaluated maintenance or induction regimens reduced statistical heterogeneity. BCG was associated with decreased risk of bladder cancer recurrence in trials that evaluated maintenance regimens (5 trials, RR 0.79, 95% CI 0.71 to 0.87,  $I^2=0\%$ ),<sup>147,151,153,111,161</sup> but not in trials that evaluated induction regimens (4 trials, RR 1.22, 95% CI 0.99 to 1.51,  $I^2=50\%$ ).<sup>111,154,156,159</sup>

There were no differences between BCG versus MMC in all-cause (7 trials, RR 0.94, 95% CI 0.83 to 1.06,  $I^2=0\%$ ) (Figure 20)<sup>147,151,153,155,157,159,161</sup> or disease-specific mortality (5 trials, RR 0.77, 95% CI 0.54 to 1.10,  $I^2=0\%$ ) (Figure 21).<sup>147,151,157,159,161</sup> There were also no differences in risk of bladder cancer progression (Figure 22) (7 trials, RR 0.88, 95% CI 0.66 to 1.17,  $I^2=18\%$ ).<sup>147,151,155-157,159,161</sup> One trial (n=337) found no difference between BCG versus MMC in risk of cystectomy, but the estimate was very imprecise (RR 2.20, 95% CI 0.07 to 65).<sup>111</sup>

There were no differences between BCG versus BCG plus MMC given sequentially in risk of all-cause (1 trial, RR 1.57, 95% CI 0.67 to 3.71)<sup>164</sup> or bladder cancer mortality (Figure 23) (2 trials, RR 1.10, 95% CI 0.50 to 2.38,  $I^2=17\%$ ),<sup>163,164</sup> bladder cancer recurrence (Figure 24) (4 trials, RR 1.03, 95% CI 0.70 to 1.52,  $I^2=75\%$ ),<sup>162-165</sup> progression (Figure 25) (3 trials, RR 0.87, 95% CI 0.40 to 1.91,  $I^2=22\%$ ),<sup>162-164</sup> or cystectomy (4 trials, RR 0.87, 95% CI 0.41 to 1.84,  $I^2=0\%$ ).<sup>162-165</sup>

Statistical heterogeneity was present in the analysis of bladder cancer recurrence. Excluding one trial that compared BCG induction therapy for 6 weeks versus BCG induction therapy plus a single dose of perioperative MMC (RR 0.53, 95% CI 0.21 to 1.37)<sup>162</sup> (rather than sequential regimens involving multiple doses of BCG and MMC) resulted in a similar estimate and did not reduce heterogeneity (RR 1.13, 95% CI 0.75 to 1.68,  $I^2=79\%$ ). Estimates were also similar using the profile likelihood method, and other subgroup and other sensitivity analyses also did not reduce heterogeneity and resulted in similar findings.

## BCG Plus MMC Versus MMC

Two trials (reported in four publications) compared MMC versus MMC and BCG given sequentially (Table 6; Appendixes E3, F2).<sup>166-169</sup> The Finnbladder study enrolled 256 patients and reported results for patients with (27%) and without CIS separately.<sup>167-169</sup> All patients

received 5 instillations of MMC and were then randomized to 15 additional instillations of MMC versus alternating MMC and BCG instillations over 2 years. The second trial analyzed 182 patients, of whom 36 percent had CIS.<sup>166</sup> Doses of BCG ranged from 50 mg to 75 mg and MMC dose from 20 mg to 40 mg. Patients received four instillations of MMC and were then randomized to 6 weekly instillations of BCG or MMC. Both trials were rated medium risk of bias.

One trial found no difference between BCG plus MMC given sequentially versus MMC alone in risk of all-cause (RR 1.53, 95% CI 0.72 to 1.74) or bladder cancer mortality (RR 0.64, 95% CI 0.22 to 1.88).<sup>166</sup> The other trial, which only reported mortality in patients with CIS, also found no difference in risk of all-cause (RR 0.95, 95% CI 0.71 to 1.30) or bladder cancer mortality (RR 0.95, 95% CI 0.45 to 1.56).<sup>167</sup>

There was no difference between BCG plus MMC given sequentially versus MMC alone in risk of bladder cancer recurrence (Figure 26) (2 trials, RR 0.88, 95% CI 0.75 to 1.03,  $I^2=0\%$ ).<sup>166-168</sup> One trial found no difference between BCG plus MMC versus MMC alone in risk of bladder cancer progression (RR 0.82, 95% CI 0.40 to 1.68).<sup>159</sup> The other trial also found no difference, but only reported data from the subgroup of patients with CIS (RR 1.28, 95% CI 0.35 to 4.61).<sup>167</sup> This trial also found no difference between BCG plus MMC given sequentially versus MMC alone in risk of cystectomy (1 trial, RR 0.20, 95% CI 0.03 to 1.57).

## **BCG Versus MMC Plus Doxorubicin**

One small trial (n=27) of patients with CIS found no differences between BCG versus sequential therapy with MMC and doxorubicin in likelihood of complete response (RR 1.06, 95% CI 0.81 to 1.39), progression (RR 1.50, 95% CI 0.28 to 8.08), or bladder cancer mortality (RR 2.21, 95% CI 0.22 to 22.5), though estimates were imprecise.<sup>145</sup> BCG was associated with decreased risk of recurrence after complete response (11% vs. 52%, RR 0.18, 95% CI 0.05 to 0.72)

## **BCG Versus Doxorubicin**

Three trials randomized patients to BCG versus doxorubicin (Table 6; Appendixes E3, F2).<sup>170-172</sup> The dose of BCG ranged from 80 mg to 150 mg and the dose of doxorubicin ranged from 20 mg to 50 mg. All trials administered maintenance therapy for patients randomized to doxorubicin, though treatment was limited to induction therapy in the BCG arm of one trial.<sup>170</sup>

One trial found no difference between BCG 150 mg versus doxorubicin in risk of all-cause mortality (all deaths were due to bladder cancer) after 3 years (RR 0.40, 95% CI 0.01 to 12), though the estimate was imprecise.<sup>172</sup> A second trial, in which half of the patients had CIS, found no difference between BCG 120 mg versus doxorubicin in risk of all-cause mortality after 5 years (RR 1.00, 95% CI 0.71 to 1.37).<sup>171</sup> Both trials found BCG associated with decreased risk of bladder cancer recurrence (13% vs. 43%, RR 0.31 [95% CI 0.16 to 0.61]<sup>172</sup> and 61% vs. 81%, RR 0.75 [95% CI 0.64 to 0.88]).<sup>171</sup> One trial found no difference between BCG versus doxorubicin in risk of bladder cancer progression (RR 0.20, 95% CI 0.02 to 1.72) or cystectomy (RR 0.26, 95% CI 0.03 to 2.46).<sup>172</sup>

## **BCG Versus Epirubicin**

Six trials (reported in 7 publications) randomized patients to BCG versus epirubicin<sup>103,173-178</sup> and three trials randomized patients to BCG versus BCG plus epirubicin given sequentially (3 studies) (Table 6; Appendixes E3, F2).<sup>179-181</sup> The dose of BCG ranged from 50 mg to 150 mg and

the dose of epirubicin from 40 mg to 80 mg. The number of bladder instillations ranged from 6 weekly instillations<sup>181</sup> to 27 over 3 years.<sup>173</sup>

BCG was associated with decreased risk of all-cause (Figure 27) (3 trials, RR 0.72, 95% CI 0.44 to 1.19,  $I^2=87\%$ )<sup>173,174,177</sup> and disease-specific mortality (Figure 28) (3 trials, RR 0.72, 95% CI 0.25 to 2.08,  $I^2=80\%$ )<sup>173,174,177</sup> versus epirubicin, but the differences were not statistically significant. Estimates were similar using the profile likelihood method. Excluding the trial<sup>173</sup> that used the lowest dose of BCG (50 mg, versus 81 mg in the other trials) reduced statistical heterogeneity for all-cause mortality (RR 0.92, 95% CI 0.67 to 1.25,  $I^2=26\%$ ), but the difference remained nonstatistically significant. Other subgroup and sensitivity analyses did not reduce statistical heterogeneity or affect findings.

BCG was associated with reduced risk of bladder cancer recurrence versus epirubicin (5 trials, 34% vs. 66%, RR 0.54, 95% CI 0.40 to 0.74,  $I^2=76\%$ ) (Figure 29).<sup>103,173-176</sup> The estimate was similar using the profile likelihood method. In stratified analyses, BCG was associated with reduced risk of recurrence in trials that excluded patients with CIS (3 trials, 33% vs. 73%, RR 0.44, 95% CI 0.36 to 0.53,  $I^2=25\%$ )<sup>173,174,176</sup> but not in trials that included patients with CIS (2 trials, RR 0.80, 95% CI 0.60 to 1.07,  $I^2=0\%$ ).<sup>103,175</sup> Other subgroup and sensitivity analyses did not reduce statistical heterogeneity or affect findings.

BCG was also associated with decreased risk of bladder cancer progression versus epirubicin, though the difference was not quite statistically significant (5 trials, RR 0.60, 95% CI 0.36 to 1.01,  $I^2=47\%$ ) (Figure 30).<sup>103,173-176</sup> Estimates and findings were similar using the profile likelihood method. Statistical heterogeneity was reduced when one trial<sup>176</sup> that used a lower dose of epirubicin (40 mg, versus 50 mg in the other trials) was excluded (4 trials, RR 0.70, 95% CI 0.48 to 1.02,  $I^2=3\%$ ). This same trial also used the fewest number of scheduled epirubicin instillations (9 versus 11-27 in the other trials). Other sensitivity and subgroup estimates had little effect on findings.

There was no difference between BCG versus BCG plus epirubicin administered sequentially in risk of bladder cancer recurrence (Figure 31) (3 trials, RR 1.25, 95% CI 0.92 to 1.69,  $I^2=0\%$ ). BCG was associated with increased risk of bladder cancer progression, but the difference was not statistically significant (3 trials, RR 1.92, 95% CI 0.73 to 5.07,  $I^2=0\%$ ) (Figure 32).<sup>179-181</sup> Excluding one trial<sup>179</sup> of maintenance therapy with BCG versus maintenance therapy with BCG plus a single dose of perioperative epirubicin resulted in similar estimates. Trials did not report mortality.

## BCG Versus Epirubicin Plus Interferon

One trial (n=256) randomized patients with newly detected stage T1, G2-G3 bladder cancer to 2 mL of OncoTICE strain BCG versus epirubicin 50 mg plus 10 MU of interferon alpha-2b given together (Table 6; Appendixes E3, F2).<sup>182,183</sup> Six weekly induction treatments were followed by maintenance therapy to 2 years. The trial was rated low risk of bias.

BCG was associated with reduced risk of bladder cancer recurrence (RR 0.66, 95% CI 0.51 to 0.85), cancer mortality at 5 years (RR 0.79, 95% CI 0.32 to 1.63), progression-free survival at 2 or 5 years, and risk of cystectomy at 2 years (RR 0.68, 95% CI 0.30 to 1.54)<sup>182,183</sup> versus epirubicin plus interferon, but the only statistically significant difference was for bladder cancer recurrence.

## BCG Versus Gemcitabine

Three trials randomized patients to BCG versus gemcitabine<sup>184-186</sup> and one trial to BCG versus BCG plus gemcitabine administered sequentially (Table 6; Appendixes E3, F2).<sup>187</sup> Two trials enrolled patients at high risk for bladder cancer recurrence (based on higher tumor grade, presence of CIS, recurrent tumors, and multiplicity of tumors),<sup>184,185</sup> one enrolled patients at intermediate risk<sup>186</sup> and one enrolled patients who were intermediate or high risk.<sup>187</sup> The dose of BCG ranged from 27 mg to 81 mg. The dose of gemcitabine was 2000 mg in all studies, although the dose immediately after TURBT was 1000 mg in one study.<sup>187</sup> The number of instillations ranged from 6 weekly instillations<sup>187</sup> to 13 instillations over 3 years.<sup>185</sup> The number of gemcitabine instillations ranged from 2<sup>187</sup> to 15 to 18.<sup>184,186</sup>

One trial found no difference between BCG versus gemcitabine in all-cause mortality, but the estimate was very imprecise (RR 1.20, 95% CI 0.04 to 34).<sup>184</sup> No trial reported bladder cancer specific mortality.

Three trials reported effects of BCG versus gemcitabine on risk of bladder cancer recurrence.<sup>184-186</sup> Due to differences between trials in the populations and BCG doses evaluated, results were not pooled. One trial of patients with high risk Ta or T1 tumors found BCG 81 mg associated with increased risk of bladder cancer recurrence versus gemcitabine (RR 1.67, 95% CI 1.21 to 2.29).<sup>184</sup> One trial of patients with high-risk T1 and/or G3 and/or CIS found no difference between BCG 50 mg and gemcitabine in risk of bladder cancer recurrence (RR 0.53, 95% CI 0.28 to 1.01).<sup>185</sup> and one trial of patients with Ta tumors without CIS or G3 disease found no difference between BCG 27 mg versus gemcitabine (RR 0.76, 95% CI 0.44 to 1.90).<sup>186</sup>

Two trials found no difference between BCG versus gemcitabine in risk of bladder cancer progression (RR 1.11 [95% CI 0.53 to 2.34]<sup>184</sup> and RR 0.52 [95% CI 0.13 to 2.06]).<sup>186</sup> One trial found no difference between BCG versus gemcitabine on all quality of life dimensions as measured by the EORTC-QLQ-C30<sup>199</sup> or the EORTC QLQ-BLS24,<sup>186</sup> with the exception that emotional functioning decreased slightly in the BCG group but improved in the gemcitabine group (p=0.03 for difference in a multivariate analysis).<sup>186</sup>

No trial of BCG versus BCG plus gemcitabine administered sequentially evaluated effects on mortality. One trial (n=87) found no difference between BCG versus BCG plus gemcitabine given sequentially in risk of bladder cancer recurrence (RR 0.86, 95% CI 0.49 to 1.51) or progression (RR 1.18, 95% CI 0.30 to 4.61).<sup>187</sup>

## BCG Versus Interferon

One trial randomized patients to BCG versus interferon alpha-2a,<sup>188</sup> one trial randomized patients to BCG versus alternating BCG plus interferon alpha-2b,<sup>189</sup> and one trial to BCG versus combination therapy with BCG plus interferon alpha-2b (Table 6; Appendixes E3, F2).<sup>190</sup> One trial administered five bladder instillations of 40 mg of MMC to all patients prior to randomization to continued BCG or BCG and interferon alpha-2b administered sequentially.<sup>189</sup> The dose of BCG ranged from 16.6 mg to 150 mg and the dose of interferon from 50 mg to 54 MU. Interferon instillations ranged from six over 1 year alternating with BCG<sup>189</sup> to 24 given in addition to BCG over 3 years.<sup>190</sup> Up to 17 interferon instillations were given over 9 months in the trial of BCG versus interferon given alone.<sup>188</sup>

One trial found BCG associated with reduced risk of recurrence versus interferon alpha-2a alone (39% vs. 69%, RR 0.57, 95% CI 0.39 to 0.82).<sup>188</sup> There were no statistically significant differences in risk of bladder cancer progression (RR 0.69, 95% CI 0.25 to 1.92) or cystectomy (RR 4.82, 95% CI 0.25 to 94), but estimates were imprecise.

One trial found BCG associated with lower risk of bladder cancer recurrence versus alternating BCG plus interferon alfa-2b (28% vs. 68%, 1 trial, RR 0.42, 95% CI 0.30 to 0.59).<sup>189</sup> All patients received MMC prior to randomization to BCG or alternating BCG plus interferon alfa-2b.

A third trial found no difference in risk of bladder cancer recurrence between BCG versus the combination of BCG plus interferon alfa-2b in patients who did not receive pretreatment with MMC (RR 0.88, 95% CI .71 to 1.08).<sup>190</sup> Patients received up to 24 instillations. The dose of BCG was approximately 50 mg during induction and 16.6 mg in the maintenance phase.

No trial of BCG versus regimens involving interferon evaluated mortality.

## **BCG Versus Thiotepa**

Two trials randomized patients to BCG versus thiotepa (Table 6; Appendixes E3, F2).<sup>142,172</sup> One trial initially enrolled patients (n=123) with Ta or T1 tumors but later restricted enrollment to T1 tumors due to the low probability of recurrence with Ta disease.<sup>172</sup> BCG-Pasteur 150 mg or thiotepa 50 mg was administered weekly for 4 weeks, then monthly for 11 months. The other trial (n=46) randomized patients with recent recurrence (up to stage T1) to 6 x 10<sup>9</sup> CFUs BCG-TICE versus thiotepa 60 mg weekly for 6 weeks, followed by maintenance therapy for a total of 2 years.<sup>142</sup> Both trials found BCG associated with reduced risk of bladder cancer recurrence versus thiotepa (13% vs. 36%, RR 0.38 [95% CI 0.19 to 0.76]<sup>172</sup> and 0% vs. 47%, RR 0.04 [95% CI 0.00 to 0.63]<sup>142</sup>). Estimates for other outcomes, including progression, death, and cystectomy, were too imprecise to evaluate effects.

## **MMC Versus Doxorubicin**

Six trials (reported in seven publications) evaluated MMC versus doxorubicin (Tables 7, 8; Appendixes E3, F2).<sup>101,112,113,115,116,144,191</sup> Three trials evaluated an MMC dose of 20 mg,<sup>112,113,116,191</sup> one trial evaluated a dose of 30 mg,<sup>101</sup> and in two trials doses ranged from 5 mg to 40 mg depending on the patient's bladder capacity.<sup>115,144</sup> In one trial, the doxorubicin dose ranged from 50 to 100 mg depending on the patient's bladder capacity.<sup>144</sup> In the other trials, doxorubicin doses ranged from 10 to 80 mg. Five trials<sup>101,112,113,115,144,191</sup> evaluated maintenance regimens (range 15 to 42 instillations) and one trial evaluated an induction regimen (8 doses over 4 weeks).<sup>112,116</sup> Duration of followup ranged from a median of 15 months to a mean of 60 months.

There was no difference between MMC versus doxorubicin in risk of bladder cancer recurrence (6 trials, RR 1.00, 95% CI 0.82 to 1.22, I<sup>2</sup>=44%) (Figure 33).<sup>112,115,116,191</sup> Findings were similar in a subgroup analysis restricted to five trials that evaluated maintenance therapy regimens (RR 0.88, 95% CI 0.69 to 1.11, I<sup>2</sup>=27%).<sup>101,112,115,144,191</sup> MMC was also associated with a decreased risk of bladder cancer progression versus doxorubicin that did not reach statistical significance (4 trials, RR 0.63, 95% CI 0.37 to 1.08, I<sup>2</sup>=20%).<sup>113,115,144,191</sup> No trial evaluated effects on overall or bladder cancer-specific mortality.

## **MMC Versus Epirubicin**

One small (n=44) trial evaluated MMC versus epirubicin in patients with single G1 or G2 tumors without CIS (Tables 7, 8; Appendixes E3, F2).<sup>192</sup> It found no difference in risk of bladder cancer recurrence at 5 years between maintenance therapy with MMC 40 mg (16 to 18 instillations over 1 year) versus either a single 80 mg dose of epirubicin (40% [6/15] vs. 36% [5/14]; RR 1.12, 95% CI 0.44 to 2.86) or maintenance therapy with epirubicin 40 mg (40%

[6/15] vs. 33% [5/15]; RR 1.20, 95% CI 0.47 to 3.10). The trial did not evaluate bladder cancer progression or mortality.

## **MMC Versus Gemcitabine**

One trial (n=109) evaluated induction therapy with MMC versus gemcitabine in patients with recurrent G1-G3 tumors (Tables 7, 8; Appendixes E3, F2).<sup>194</sup> At a median followup of 36 months, there was no difference between MMC versus gemcitabine in risk of bladder cancer recurrence (p=0.29), but MMC was associated with lower likelihood of recurrence-free survival (log-rank test, p=0.0021). MMC was also associated with increased risk of bladder cancer progression, but the difference was not statistically significant (18% [10/55] vs. 11% [6/54]; RR 1.64, 95% CI 0.64 to 4.19). The trial did not assess mortality.

## **MMC Versus Interferon Alpha**

One trial (n=287) evaluated induction therapy with MMC versus interferon-alpha for primary G1 or G2 tumors without CIS (Tables 7, 8; Appendixes E3, F2).<sup>193</sup> It found MMC associated with lower risk of bladder cancer recurrence than interferon-alpha 50 MU after 42 months of followup (37% [52/141] vs. 48% [70/146]; RR 0.77, 95% CI 0.58 to 1.01). MMC was associated with increased risk of bladder cancer progression, but the difference was not statistically significant (6% [8/141] vs. 4% [6/146], RR 1.38, 95% CI 0.49 to 3.88).<sup>193</sup> The trial did not assess effects on mortality.

## **MMC Versus Interferon Gamma**

One trial (n=123) evaluated maintenance therapy (20 instillations over 1 year) with MMC 40 mg versus interferon-gamma 15 MU for primary G2 tumors (CIS excluded) (Tables 7, 8; Appendixes E3, F2).<sup>141</sup> MMC was associated with higher risk of recurrence after a median of 2 years followup [43% (27/63) vs. 27% (16/60); RR 1.61, 95% CI 0.97 to 2.67]. The trial did not assess effects on bladder cancer progression or mortality.

## **MMC Versus Thiotepa**

Two trials compared maintenance therapy with MMC 40 mg versus thiotepa 60 mg.<sup>143,146</sup> One trial (n=47) of patients with recurrent or multiple bladder cancers (excluding Tis) reported no clear differences in risk of recurrence (RR 1.76, 95% CI 0.36 to 8.70) or progression (RR 2.64, 95% CI 0.30 to 23.6), but estimates were very imprecise.<sup>143</sup> Another trial (n=83) of patients with Ta or Tis lesions (not necessarily recurrent or multiple) found no difference in risk of recurrence (33% vs. 29%, RR 1.14, 95% CI 0.60 to 2.16).<sup>146</sup>

## **Doxorubicin Versus Epirubicin**

Three trials evaluated doxorubicin versus epirubicin (Tables 9, 10; Appendixes E3, F2).<sup>119,195,196</sup> Doses of doxorubicin were 30 to 50 mg and doses of epirubicin 30 to 80 mg. All trials evaluated maintenance regimens.

Doxorubicin was associated with higher risk of recurrence versus epirubicin (3 trials, RR 1.56, 95% CI 1.08 to 2.22,  $I^2=0.0$ ).<sup>119,195,196</sup> One trial found no difference between maintenance therapy with doxorubicin 50 mg versus epirubicin 50 mg (RR 0.91, 95% CI 0.33 to 2.57) or epirubicin 80 mg (RR 2.08, 95% CI 1.13 to 3.83) in risk of bladder cancer progression<sup>119</sup> and another trial reported no instances of progression in either treatment group.<sup>196</sup> None of the trials evaluated effects on mortality.

## **Doxorubicin Versus Thiotepa**

One trial (n=109) evaluated maintenance therapy (15 instillations over 1 year) with doxorubicin 50 mg versus thiotepa 50 mg in patients with G1-G3 NMIBC (Tables 9, 10; Appendixes E3, F2).<sup>172</sup> There were no statistically significant differences in risk of bladder cancer recurrence (43% [23/53] vs. 36% [20/56]; RR 1.22, 95% CI 0.76 to 1.94) progression (8% [4/53] vs. 4% [2/56]; RR 2.11, 95% CI 0.40 to 11.06), noncancer mortality (0% [0/53] vs. 2% [1/56]; RR 0.35, 95% CI 0.01 to 8.45) or cancer-specific mortality (2% [1/53] vs. 0% [0/56]; RR 3.17, 95% CI 0.13 to 76.07) after a median followup of 36 months, though estimates were very imprecise.

## **Epirubicin Versus Interferon Alpha**

One trial (n=134) evaluated a single instillation of epirubicin 100 mg versus interferon-alpha 50 MU for primary G1-G3 tumors (Tables 11, 12; Appendixes E3, F2).<sup>132,133</sup> Epirubicin was associated with decreased risk of bladder cancer recurrence (46% [31/68] vs. 68% [45/66]; RR 0.67, 95% CI 0.49 to 0.91). Effects on bladder cancer progression or mortality were not reported.

**Figure 19. Meta-analysis of bacillus Calmette-Guérin versus MMC: Risk of recurrence**

BCG = bacillus Calmette-Guérin; CI = confidence interval; MMC = Mitomycin C  
 Note: Witjes, 1996 and Ojea, 2007 each reported effects for two different regimens.

Note: Akaza, 1987 (Study 2) and Nijima, 1983 (Study 1) each reported effects for two different regimens and Huland, 1990 reported effects for three different regimens.

**Key Question 3b. Does the comparative effectiveness differ according to tumor characteristics, such as stage, grade, size, multiplicity, whether the tumor is primary or recurrent, or molecular/genetic markers?**

## Key Points

- There were no clear differences in estimates of effectiveness of intravesical therapies in subgroups defined by tumor stage, grade, size, multiplicity, recurrence status, or DNA ploidy (SOE: low for stage, grade, tumor multiplicity, primary versus recurrent DNA ploidy).

## Detailed Synthesis

Evidence on how estimates of comparative effectiveness of intravesical therapies vary in subgroups defined by tumor characteristics was limited. There were no clear differences in

estimates of effectiveness in subgroups defined by tumor stage,<sup>103,106,112,119,130,132,133,136,137,139,172,180,191,193-195</sup> presence or absence of CIS,<sup>152,159,171,172</sup> tumor grade,<sup>103,112,119,130,132,133,135-137,139,155,172,173,188,191,194,195</sup> tumor multiplicity,<sup>101,103,119,128,130,132,133,135,139,172,180,188,194,195</sup> tumor size,<sup>180,188,194</sup> primary versus recurrent tumor,<sup>100,103,112,119,122,124,128,130-133,135,180,191,194,195</sup> or DNA ploidy.<sup>180</sup> The trials evaluated various intravesical therapies, comparisons, and outcomes (recurrence, progression, mortality). Risk estimates were generally similar across subgroups or were imprecise, with overlapping confidence intervals.

**Key Question 3c. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities?**

## Key Points

- No trial evaluated how estimates of effectiveness of intravesical therapy vary in subgroups defined by patient characteristics such as age, sex, race/ethnicity, performance status, and comorbidities (SOE: insufficient).
- In patients with recurrence or progression following prior BCG therapy, one trial found maintenance therapy with gemcitabine associated with decreased risk of recurrence versus repeat treatment with BCG, and one trial found MMC maintenance therapy associated with lower likelihood of disease-free survival than gemcitabine; estimates for progression were imprecise (SOE: low).

No trial evaluated how estimates of effectiveness of intravesical therapy vary in subgroups defined by patient characteristics such as age, sex, race/ethnicity, performance status, and comorbidities. Most trials of patients with recurrent bladder cancer did not specify whether patients had received prior intravesical therapy or the type of intravesical therapy received.<sup>109,149,165,168,179,180,188,189,196</sup> One trial of patients with high-risk Ta or T1 NMIBC (based on the European Organization for Research and Treatment of Cancer Scoring System) who failed BCG therapy found a gemcitabine maintenance regimen with gemcitabine (2000 mg) associated with decreased risk of recurrence versus BCG-Connaught (81 mg) (53% vs. 88%, RR 0.60, 95% CI 0.44 to 0.82), though there was no difference in risk of progression (33% vs. 38%) and only one death was recorded.<sup>184</sup> Another trial (n=109) of patients with progression or relapse after intravesical therapy (83% BCG) found an MMC maintenance regimen associated with lower likelihood of disease-free survival (p=0.0021) than gemcitabine, though differences in recurrence rate (1.72 vs. 1.26 per 100 patient-months, p=0.31) and progression (18% vs. 11%, RR 1.64, 95% CI 0.64 to 4.19) were not statistically significant.<sup>194</sup>

Key Question 3d. Does the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents differ according to dosing frequency, duration of treatment, and/or the timing of administration relative to TURBT?

## Key Points

### BCG

- Six trials found no clear differences between standard and lower doses of BCG in risk of recurrence, progression, or bladder cancer mortality, including in patients with higher-risk NMIBC, though there was some inconsistency between trials. Standard therapy was associated with increased risk of local and systemic adverse events versus lower dose BCG in most trials (SOE: low).
- Three trials of responders to BCG induction therapy found no clear differences between maintenance versus no maintenance therapy in risk of all-cause mortality (3 trials, RR 0.90, 95% CI 0.72 to 1.11) or bladder cancer mortality (2 trials, RR 1.14, 95% CI 0.24 to 5.40), though maintenance therapy was associated with decreased risk of recurrence (RR 0.76 [95% CI 0.65 to 0.88] and RR 0.16 [95% CI 0.02 to 1.21]) (SOE: low).
- Two of three trials found more prolonged courses of BCG associated with decreased risk of bladder cancer recurrence versus induction therapy in patients with higher-risk NMIBC, but increased risk of adverse events (SOE: low).
- One trial found BCG TICE associated with lower likelihood of 5-year recurrence-free survival versus BCG Connaught (48% vs. 74%,  $p=0.01$ ) and one trial found BCG TICE associated with lower likelihood of 5-year recurrence-free survival versus BCG RIVM (36% vs. 54%,  $p=0.07$ ). Four trials that compared non-TICE BCG strains found no differences (SOE: low).

### MMC

- One trial of patients with NMIBC (not selected for being at higher risk) found no clear differences between MMC 40 mg single instillation versus five instillations in risk of recurrence, progression, or mortality. The single instillation was associated with lower risk of local adverse events (SOE: low).
- One trial of patients with higher-risk NMIBC found MMC 20 mg induction therapy for 6 weeks associated with higher risk of recurrence than maintenance therapy. There were no clear differences in risk of adverse events (SOE: low).
- Two trials of MMC maintenance regimens in patients with NMIBC not selected for being at higher risk found some evidence that a higher total number of instillations and increased frequency during initial therapy were associated with lower risk of recurrence and progression, and might be associated with lower risk of local adverse events (SOE: low).
- One trial found no difference between “optimized” versus nonoptimized administration of intravesical MMC in risk of recurrence in patients with low-risk NMIBC, but one other trial of patients with higher-risk NMIBC found optimized administration associated with lower risk of recurrence and increased risk of local adverse events (SOE: low).

## **Doxorubicin**

- Two trials of patients with NMIBC not selected for being at higher risk found no differences between doxorubicin 30 mg and 20 mg given as short (8 week) or long (2 years) regimens in risk of recurrence or progression, with no differences in adverse events (SOE: low).
- Two trials of patients with NMIBC not selected for being at higher risk found no clear differences between doxorubicin induction therapy and induction plus maintenance in risk of recurrence, progression, or mortality, with no differences in adverse events (SOE: low).
- Two trials of doxorubicin found no clear benefits associated with administration prior to TURBT or multiple instillations immediately after TURBT, with some evidence of increased adverse events with multiple immediate post-TURBT instillations (SOE: low).

## **Epirubicin**

- Three trials of epirubicin found no clear evidence that higher doses are associated with reduced risk of recurrence or progression versus lower doses, with no differences in adverse events (SOE: moderate).
- Three trials found no clear difference between single instillation epirubicin and multiple instillations in patients with low- or high-risk NMIBC in risk of recurrence, progression, or bladder cancer mortality, with some evidence of lower risk of local adverse events (SOE: moderate).
- Two trials found no clear differences between epirubicin maintenance therapy and induction without maintenance in risk of recurrence or progression, including one trial of patients with higher-risk NMIBC. There were no differences in risk of local adverse events (SOE: moderate).
- Five trials that evaluated different epirubicin regimens that included maintenance therapy found some evidence that more intensive therapy is associated with decreased risk of recurrence, but results were inconsistent. There was no difference in risk of adverse events (SOE: low).

## **Thiotepa**

- Two trials found no clear differences between thiotepa 30 mg and 60 mg for maintenance or for treatment of incompletely resected NMIBC or CIS (SOE: low).

## **Interferon Alpha-2b**

- Four trials found higher doses of interferon alfa-2b associated with improved outcomes related to recurrence, progression, or resolution of bladder cancer marker lesions versus lower doses, but most estimates were imprecise and did not reach statistical significance. There were no clear differences in risk of local or systemic adverse events (SOE: low).

## **Multiple Drugs**

- One trial found no difference between initiation of intravesical therapy (9 instillations over 6 months) with MMC or doxorubicin 50 mg on the day of TURBT versus 1 to 2 weeks after TURBT in risk of recurrence, progression, or mortality; or between maintenance beyond 6 months versus no additional maintenance therapy. There were no clear differences in local or systemic adverse events (SOE: low).

## Detailed Synthesis

Fifty-three trials in 57 publications of intravesical therapy compared different doses or instillation regimens of the same drug or different BCG strains (Tables 17, 18; Appendixes E4, F2).<sup>112,113,116,118,119,123,126,134,136,140,148,151,154,156,157,176,191,192,197,198,200-236</sup> Eleven trials in 12 publications evaluated comparisons involving BCG,<sup>148,151,156,176,200,201,204-211,215,218,222,223,226,228,230,233,237</sup> seven trials evaluated MMC,<sup>118,154,191,197,198,212,213,232</sup> five trials in six publications evaluated doxorubicin,<sup>112,113,116,123,214,231,236</sup> 13 trials evaluated epirubicin,<sup>119,126,134,192,216,219,220,224,225,227,229,234,235</sup> two trials in one publication evaluated thiotepa,<sup>140</sup> and three trials evaluated interferon alpha-2b.<sup>136,203,217,221</sup> Sample sizes ranged from 34 to 1,355 and duration of followup from 4 weeks to 9 years. Twenty-four trials were conducted in the United States or Europe.<sup>118,136,140,148,151,154,156,191,197,212,214,216,217,221-224,228,230-232,234</sup> Thirty-eight trials were rated medium risk of bias<sup>112,113,116,118,119,123,126,134,136,140,148,151,154,156,176,191,192,197,212,214-217,219-225,227-229,231-236</sup> and four trials high risk of bias.<sup>198,218,226,230</sup> No trial reported blinding of patients or care providers to the treatment regimen received. Only five trials<sup>118,134,176,215,233</sup> reported in adequate detail use of an appropriate randomization method and only one trial<sup>221</sup> reported assessment of outcomes blinded to the treatment received. Additional methodological shortcomings in the trials rated high risk of bias included use of sequential allocation<sup>218,226</sup> and reporting of only interim results.<sup>230</sup>

## BCG

### Comparisons of Different Doses

Seven trials (reported in eight publications) compared different doses of intravesical BCG.<sup>151,218,222,223,226,228,230,237</sup> The trials varied with regard to the BCG strain, dose comparisons, and populations evaluated. Most trials found no clear differences between standard and lower doses of BCG in risk of recurrence and other outcomes, though there was some inconsistency across studies.

Three trials compared different doses of intravesical Connaught strain BCG.<sup>151,222,223</sup> In all three trials, BCG was administered as 12 instillations over 5 to 6 months. One trial (n=499) found no differences between standard (81 mg) and reduced (27 mg) dose Connaught strain BCG in risk of recurrence (28% vs. 31%, RR 0.92, 95% CI 0.70 to 1.20), progression (12% vs. 13%, RR 0.86, 95% CI 0.54 to 1.37), or bladder cancer mortality (7.9% vs. 7.3%, RR 1.09, 95% CI 0.59 to 2.01) after a median of 69 months.<sup>222</sup> In the subgroup of patients with high-risk (T1G3, Tis,  $\geq 2$  prior relapses, multifocal, or  $\geq 3$  cm) tumors, there was a nonstatistically significant trend favoring standard (81 mg) dose therapy (30% vs. 37%, RR 0.80, 95% CI 0.60 to 1.08), but the estimate was imprecise and there were baseline differences in risk markers. In addition, a subsequent randomized trial (n=155) that focused on patients with higher-risk NMIBC (T1G3 and Tis) found no differences between standard dose versus 27 mg in risk of recurrence (39% vs. 45%, RR 0.86, 95% CI 0.60 to 1.25), progression (24% vs. 26%, RR 0.94, 95% CI 0.54 to 1.61), or bladder cancer mortality (12% vs. 15%, RR 0.81, 95% CI 0.36 to 1.79) after a median followup of 60 months.<sup>223</sup> The third trial, which enrolled patients with intermediate-risk (TaG2 or T1/G1-2 without CIS) tumors, found no statistically significant differences between one-third dose (27 mg) and one-sixth dose (13.5 mg) in risk of recurrence (27% vs. 36%, RR 0.74, 95% CI 0.52 to 1.06), progression (10% vs. 13%, RR 0.76, 95% CI 0.39 to 1.47), or bladder cancer mortality (2.1% vs. 3.6%, RR 0.59, 95% CI 0.14 to 2.41), though trends favored the higher dose group.<sup>151</sup>

Four trials evaluated dose comparisons involving other BCG strains.<sup>218,226,228,230</sup> One trial, which did not focus on high-risk NMIBC, found no differences between low (40 mg) versus standard (80 mg) dose Tokyo 172 strain BCG (6 instillations over 6 weeks) in risk of recurrence (28% vs. 16%, RR 1.71, 95% CI 0.66 to 4.40) or progression (5.0% vs. 6.4%, RR 0.78, 95% CI 0.12 to 5.20) after about 2 years followup.<sup>218</sup> The other three trials focused on treatment of higher-risk NMIBC. The largest trial (n=1805) enrolled patients with solitary T1G3 or multiple Ta-T1/G1-G3 tumors.<sup>228</sup> It found no differences between one third versus full dose OncoTICE strain BCG (administered as 15 instillations over 12 months or 27 instillations over 36 months) in the likelihood of remaining recurrence-free at 5 years (59% vs. 62%, p=0.09), progression, or mortality. However, the one-third dose/1 year regimen was associated with decreased likelihood of remaining disease-free versus the full dose/3 year regimen (HR 0.75, 95% CI 0.59 to 0.94). Benefits of three years of full-dose therapy were limited to high-risk patients (HR for recurrence 1.61, 95% CI 1.13 to 2.30). One trial (n=97) of patients with residual T1 or Tis tumors or a history of multiple recurrences found low-dose Armand Frappier BCG (60 mg) associated with lower likelihood of remaining recurrence-free (37% vs. 67%, RR 0.55, 95% CI 0.36 to 0.84) than standard dose therapy (each administered once weekly for 6 weeks) after a mean duration of followup of 21 months.<sup>226</sup> The other trial (n=183), which enrolled patients with multiple Ta/T1 tumors or CIS, found low-dose (75 mg) Pasteur strain BCG more effective than standard (150 mg) dose (6 weeks induction with 2 years maintenance) in time to recurrence (p=0.0009 overall), but there was no difference in risk of tumor progression (9% in both groups).<sup>230</sup> In addition, only interim results have been published from this trial.

In most trials, standard dose BCG therapy was consistently associated with increased risk of local and systemic adverse events versus reduced doses.<sup>218,222,223,226</sup> However, the largest trial found no clear differences between standard versus 1/3 dose BCG in local or systemic adverse events, or in risk of discontinuation due to adverse events.<sup>228,237</sup> One trial found no differences between 27 (1/3 dose) versus 13.5 mg (1/6 dose) in local or systemic adverse events.<sup>151</sup>

## Comparisons of Different Instillation Regimens

Six trials (reported in seven publications) compared induction therapy with BCG for 6 to 8 weeks versus more prolonged courses.<sup>176,200,205-207,209,215</sup> Three trials randomized responders to BCG induction therapy (dose 80 to 81 mg) to maintenance therapy versus no maintenance therapy.<sup>205-207,209</sup> Maintenance therapy ranged from 3 additional instillations over 9 months to 21 additional instillations over 3 years. There was no difference between maintenance therapy versus no maintenance therapy in risk of all-cause mortality (3 trials, RR 0.90, 95% CI 0.72 to 1.11,  $I^2=0\%$ ),<sup>205,206,209</sup> bladder cancer mortality (2 trials, RR 1.14, 95% CI 0.24 to 5.40,  $I^2=0\%$ ),<sup>205,209</sup> or progression (2 trials, RR 0.85, 95% CI 0.69 to 1.04).<sup>205,206</sup> Two trials each found maintenance therapy associated with decreased risk of recurrence (RR 0.76 [95% CI 0.65 to 0.88]<sup>206</sup> and RR 0.16 [95% CI 0.02 to 1.21]<sup>205</sup>), but there was statistical heterogeneity and the pooled estimate was imprecise, with a nonstatistically significant effect (RR 0.49, 95% CI 0.12 to 1.93,  $I^2=56\%$ ). None of the trials reported risk of adverse events with maintenance therapy versus no maintenance therapy.

Three other trials randomized patients with high-risk (recurrent or multifocal) NMIBC to maintenance versus induction therapy with BCG, prior to determining response to induction therapy.<sup>176,200,215</sup> In one trial (n=83), maintenance therapy with Connaught strain BCG 81 mg (6 weeks induction followed by once weekly instillations for 3 weeks at 3, 6, 12, and 18 months) was associated with lower risk of recurrence (12% vs. 33%, RR 0.37, 95% CI 0.14 to 0.92) than

induction therapy alone after a median followup of 2 years.<sup>176</sup> In another trial (n=70), a 12-week course of Pasteur strain BCG 120 mg was associated with a trend towards decreased risk of recurrence versus a 6-week course after 2 years, but the difference was not statistically significant (30% vs. 45%, RR 0.67, 95% CI 0.35 to 1.27).<sup>215</sup> The third trial found no difference between monthly maintenance therapy with Pasteur strain BCG 120 mg versus a 6-week course of therapy in disease-free interval after a median followup of 22 months.<sup>200</sup> One trial<sup>176</sup> found no difference in risk of progression (0% vs. 6.1%, RR 0.15, 95% CI 0.01 to 2.7), one trial<sup>215</sup> found no differences in risk of mortality or radical cystectomy, and one trial reported no difference in risk of progression (there were no deaths),<sup>200</sup> but estimates were imprecise. Two trials reported risk of harms with maintenance versus induction therapy. In both trials, more prolonged courses of BCG therapy were associated with increased risk of local adverse events versus 6-week induction regimens, with no clear differences in systemic or serious adverse events.<sup>176,215</sup> In the trial of 18 months maintenance versus 6 weeks of induction therapy, rates of urinary frequency were 93 versus 71 percent (RR 1.3, 95% CI 1.1 to 1.6), dysuria 93 versus 69 percent (RR 1.3, 95% CI 1.1 to 1.7), hematuria 93 versus 71 percent (RR 1.3, 95% CI 1.1 to 1.6), and fever 43 versus 26 percent (RR 1.6, 95% CI 0.88 to 3.0).<sup>176</sup> In the trial of 12 versus 6 weeks of BCG, there were fewer adverse events and differences were not statistically significant.<sup>215</sup>

One trial of patients with solitary T1G3 or multiple Ta-T1/G1-G3 tumors found no difference between OncoTICE strain BCG (1/3 or full dose) administered as 15 instillations over 12 months versus 27 instillations over 36 months in the likelihood of remaining recurrence-free at 5 years (57% vs. 63%, p=0.06).<sup>228</sup> There were also no differences in risk of progression or mortality. There were no differences in risk of local or systemic adverse events.<sup>228,237</sup>

## Comparisons of Different BCG Strains

Six trials (reported in eight publications) compared outcomes of 6 to 8 weeks of intravesical therapy with one BCG strain versus another.<sup>148,156,201,204,208,210,211,233,238</sup> The largest trial (n=437) found BCG TICE associated with lower likelihood of remaining recurrence-free after 5 years (36% vs. 54%, log-rank p=0.07) in patients with papillary NMIBC (not selected for being higher risk), though the difference was not statistically significant.<sup>148,156,211</sup> There was no difference in risk of progression (5% vs. 6%) or local or systemic side adverse events. The differences also were not statistically significant when analyses were restricted to patients with G3 tumors or CIS. Another trial (n=142) found BCG TICE associated with lower likelihood of 5-year recurrence-free survival versus BCG Connaught (48% vs. 74%, p=0.01) in higher-risk patients (high-grade tumors, low-grade tumor with multiple recurrences, or CIS), though there were no difference in progression-free or overall survival.<sup>210</sup> BCG TICE was also associated with higher risk of dysuria (30% vs. 13%, p=0.02), though there was no difference in risk of any harm.

Four other trials found no differences between non-TICE BCG strains.<sup>201,204,208,233,238</sup> Two trials focused on patients with multiple recurrent tumors and two included patients with CIS. One trial (n=129)<sup>233</sup> found no difference between BCG Tokyo versus BCG Connaught in likelihood of 5-year recurrence-free survival (62% vs. 56%, p=0.74). A smaller trial (n=38) also found no differences between low-dose BCG Tokyo versus regular dose BCG Connaught in likelihood of complete response (72% vs. 75%) at median followup of 16.5 months or in likelihood of 1-year recurrence-free survival (p=0.69).<sup>204</sup> One trial (n=94)<sup>201</sup> found no difference between BCG Evans versus BCG Pasteur in marker tumor clearance or development of new tumors after 3 months. Another trial found no difference between BCG Evans (Glaxo) versus BCG Pasteur in likelihood of a complete response at 1 year (42% vs. 44%), but enrolled a very small sample

(n=21).<sup>208,238</sup> There were no differences in risk of adverse events in any of these BCG comparisons.

## **MMC**

### **Comparisons of Different Instillation Regimens**

One trial (n=295) of patients with NMIBC (not selected for being at higher risk) found no clear differences between MMC 40 mg single instillation within 24 hours of TURBT versus 5 instillations in risk of recurrence at 24 months (42% vs. 31%,  $p=0.14$ ), progression-free interval (HR 0.97, 95% CI 0.46 to 2.06), all-cause mortality (34% vs. 42%, RR 0.79, 95% CI 0.59 to 1.1), or bladder cancer mortality (5.4% vs. 5.5%, RR 0.98, 95% CI 0.38 to 2.5).<sup>118</sup> The single instillation was associated with lower risk of dysuria or frequency (0% vs. 6.2%, RR 0.05, 95% CI 0.003 to 0.88).

One trial (n=332) of patients with higher-risk NMIBC (based on higher stage, higher grade, multifocality, and recurrence) found MMC 20 mg induction therapy for 6 weeks associated with higher risk of recurrence than induction plus maintenance therapy for 3 years (26% vs. 10%, RR 2.5, 95% CI 1.5 to 4.2).<sup>154</sup> There were no clear difference in risk of adverse events.

Two trials compared MMC regimens that varied in both the number and frequency of instillations in patients with NMIBC who were not selected for being at higher risk. One trial (n=380) found that regimens of MMC 20 mg that involved more intensive induction (weekly for 8 weeks followed by maintenance for a total of 3 years or weekly for 20 weeks) were associated with lower risk of recurrence and progression than regimen involving less intensive (biweekly for 1 year, followed by maintenance for a total of 3 years) induction (18% and 20% vs. 24% for recurrence and 5.2% and 6.7% vs. 12% for progression, respectively).<sup>232</sup> Effects were more pronounced in patients with recurrent than with primary bladder cancer. Adverse events were not reported. Another trial found that a more intensive and prolonged course of MMC 20 mg (induction with 8 weekly instillations, with a total of 42 instillations over 3 years) was associated with lower risk of recurrence and stage progression than the same number of instillations over 3 years with a less intense induction (biweekly for the first year) or a course involving 20 weekly instillations (recurrence 9.4% vs. 15% and 17%; stage progression 1.0% vs. 2.9% and 5.3%), and a lower risk of chemical cystitis (12% vs. 25% and 18%).<sup>191</sup>

One trial (n=54) of MMC (40 mg) for patients with recurrent, single, small (<1.5 cm) NMIBC found 3 instillations per week for 2 weeks prior to TURBT associated with higher likelihood of complete response (absence of residual tumor) versus a once weekly instillation for 6 weeks prior to TURBT, though the difference was not statistically significant (70% vs. 44%, RR 1.58, 95% CI 0.97 to 2.56).<sup>213</sup> There were no cases of progression. There were no differences in risk of urinary frequency, chemical cystitis, or hematuria.

### **“Optimized” Versus Nonoptimized Administration**

Two trials compared “optimized” administration of intravesical MMC (through alkalization of urine) versus instillation without additional optimization.<sup>197,198</sup> One of the trials also optimized MMC administration by restricting fluids and emptying the bladder prior to instillation, and administering at a higher dose and concentration (40 mg in 20 mL versus 20 mg in 20 mL).<sup>197</sup> The first trial (n=26), which evaluated single-dose MMC for low-risk NMIBC (Ta, G1, solitary, <3 cm), found no difference between optimized and standard administration of a single dose of MMC, with no cases of recurrence in the standard therapy group after a median duration of

followup of 51 months.<sup>198</sup> However, a trial (n=201) of high-risk NMIBC found optimized therapy associated with lower risk of recurrence (51% vs. 66%; RR 0.78, 95% CI 0.63 to 0.97) and time to recurrence (median 29 vs. 12 months, p=0.005) after 5 years of followup. Benefits were not observed in patients with prior intravesical therapy, but were observed across other subgroups defined by tumor multifocality, stage, grade, and papillary lesion type. Optimized therapy was associated with increased risk of dysuria (33% vs. 18%, RR 1.86, 95% CI 1.15 to 3.02), with no difference in risk of other local or systemic adverse events and no difference in risk of discontinuation due to adverse events (1.8% vs. 1.9%).

## **Doxorubicin**

### **Comparisons of Different Doses**

Two trials found no differences between regimens involving doxorubicin 30 mg versus 20 mg in patients with NMIBC not selected for being at higher risk. One trial (n=368) of short-term therapy (eight instillations over 4 weeks) found no differences between doses in recurrence-free survival at 540 days (57% vs. 52% for 30 mg vs. 20 mg doses, respectively) or at 1800 days.<sup>112,116</sup> The other trial (n=345), which evaluated longer-term therapy (21 instillations over 2 years), found no difference in recurrence-free survival (62% vs. 59%) at 2 years.<sup>112,113</sup> In a subgroup of patients with long-term followup data (median 6.6 years) it also found no difference in risk of progression (43% vs. 31%) or recurrence rate (0.473 vs. 0.512 per year). In both trials, there were no clear differences in local adverse events and no systemic adverse events were reported.

### **Comparisons of Different Instillation Regimens**

Two trials found no clear differences between doxorubicin induction therapy and induction plus maintenance in patients with NMIBC not selected for being at higher risk. One trial (n=146) found no difference between doxorubicin 50 mg maintenance therapy for 2 years versus induction therapy for 6 weeks without maintenance in risk of recurrence (47% vs. 42%, RR 1.1, 95% CI 0.78 to 1.6), progression (19% vs. 20%, RR 0.94, 95% CI 0.48 to 1.8), or bladder cancer mortality (13% vs. 13%, RR 0.95, 95% CI 0.41 to 2.2) after 5 years.<sup>214</sup> There were also no clear difference in risk of recurrence in subgroups stratified by primary or recurrent, solitary or multiple, or Ta vs. T1 cancers. Rates of local adverse events (chemical cystitis) were similar (13% vs. 12%). The other trial (n=220) found no differences between doxorubicin 50 mg given as 13 instillations over 6 weeks versus 28 instillations over 6 months in recurrence rate (25 vs. 2.3 per 100 patient-months), progression (16% vs. 11%, p>0.35), or bladder cancer mortality (5.3% vs. 1.8%).<sup>231</sup>

Two trials of doxorubicin involved comparisons regarding timing of therapy.<sup>123</sup> One trial (n=306) of patients with higher-risk NMIBC (multiple or recurrent lesions) found maintenance therapy with doxorubicin 20 mg (21 instillations over 2 years) associated with higher likelihood of remaining recurrence-free at 2 years (38% vs. 19%, p<0.05) than 6 instillations administered in the 2 weeks prior to TURBT, with no post-TURBT therapy.<sup>123</sup> There were no differences in risk of local adverse events. The other trial (n=187), which did not focus on higher-risk NMIBC, evaluated four regimens of doxorubicin 30 mg involving early initiation (two instillations in first 2 days, followed by 17 instillations over 1 year) versus no early instillation (17 instillations over 1 year, starting 7 days after TURBT), with or without 5-fluorouracil.<sup>236</sup> As no effects of 5-fluorouracil on outcomes were observed, these groups were combined for the analyses. The trial

found no overall difference between the early and delayed initiation groups in likelihood of remaining recurrence-free at 36 months (76% vs. 65%,  $p>0.05$ ), though estimates favored the early initiation groups at some earlier time points and in patient subgroups with primary tumors, Ta, <1 cm lesions, G1 lesions, G2 lesions, and multiple tumors. Risk of bladder irritation was greater with the early instillation regimens (48-55% vs. 26%), but there was no difference in risk of bladder irritation resulting in withdrawal (5-8% vs. 2-3%).

## Epirubicin

### Comparisons of Different Doses

Three trials compared regimens involving different doses of intravesical epirubicin.<sup>119,134,224</sup> Overall there was no clear pattern that higher doses of epirubicin are associated with improved outcomes. One trial ( $n=132$ ) of patients with higher-risk NMIBC found no statistically significant differences between epirubicin 50 mg vs. 80 mg, given as ~19 instillations over 1 year, in risk of recurrence (25% vs. 18%; RR 1.42, 95% CI 0.73 to 2.76), time to first recurrence (mean 16 vs. 15 months), or risk of progression (11% vs. 4.4%, RR 2.5, 95% CI 0.67 to 9.2) after a mean followup of 30 months, though trends favored higher-dose therapy.<sup>126</sup> Lower-dose therapy was associated with a higher recurrence rate (0.83 vs. 0.60 per 100 patient-months,  $p<0.05$ ). Two other trials evaluated patients with NMIBC not selected for being at higher risk.<sup>134,224</sup> One trial ( $n=54$ ) found no differences between epirubicin 50 mg vs. 100 mg (administered as 5 instillations over 1 year) in risk of recurrence (44% vs. 56%, HR 0.68, 95% CI 0.41 to 1.13) or recurrence rate (0.52 vs. 0.58 per patient-year,  $p>0.05$ ) after mean followup of about 2 years.<sup>224</sup> The other trial ( $n=163$ ) found no differences between epirubicin 20 mg vs. 50 mg (administered as 2 instillations, one immediately after TURBT and one the following day) in duration of recurrence-free survival (mean 24 vs. 38 months,  $p>0.05$ ) or risk of progression (0% vs. 1.1%) after a median followup duration of 44 months.<sup>134</sup> One of the trials found lower-dose therapy associated with lower risk of bladder spasm (15% vs. 44%, RR 0.33, 95% CI 0.17 to 0.65);<sup>224</sup> otherwise there were no clear differences in risk of local or systemic adverse events.

### Comparisons of Different Instillation Regimens

Three trials compared epirubicin single instillation therapy with multiple instillations.<sup>119,192,235</sup> One trial ( $n=143$ ) of patients with low-risk NMIBC found no difference between a single instillation of epirubicin 100 mg within 6 hours of TURBT versus an additional instillation at 12 hours in risk of recurrence (15% vs. 21%, adjusted HR 0.67, 95% CI 0.30 to 1.51) or progression (1.5% vs. 4.0%, RR 0.37, 95% CI 0.04 to 3.45) after a mean followup duration of 16.9 months.<sup>235</sup> Another trial ( $n=44$ ) of patients with Ta-T1/G1-G2 NMIBC found no differences between a single intravesical instillation of epirubicin 80 mg given within 6 hours of TURBT versus maintenance therapy with epirubicin 40 mg over about 1 year in risk or recurrence (36% vs. 33%, RR 1.07, 95% CI 0.39 to 2.92) or tumor-free survival (64% vs. 67%, RR 0.96, 95% CI 0.57 to 1.64) through 5 years.<sup>192</sup> Although the single instillation regimen was associated with lower risk of any side effect, there were no clear differences in risk of specific local adverse events and no systemic adverse events were recorded. The other trial ( $n=114$ ), which evaluated patients with higher-risk NMIBC, found no difference between a single instillation of epirubicin 50 mg immediately after TURBT versus treatments initiated after 1 to 2 weeks and continued for 1 year (18 instillations) in risk of recurrence (24% vs. 25%), time to first recurrence (16 vs. 18 months), or risk of progression (5.5% vs. 3.4%) after a mean duration

of followup of 32 months.<sup>119</sup> There were also no clear differences in risk of recurrence in subgroups stratified by tumor stage, grade, or lesion size, though results favored delayed maintenance therapy for G3 lesions (53% vs. 20%, RR 2.63, 95% CI 0.88 to 7.89). There were no differences in risk of adverse events, including adverse events requiring temporary or permanent discontinuation of therapy.

Two trials evaluated epirubicin maintenance therapy versus induction without maintenance.<sup>229,234</sup> One trial (n=395) of patients with higher-risk, non-G3 NMIBC (multiple or recurrent tumors) found no clear differences between epirubicin 80 mg maintenance therapy (16 instillations over 1 year) versus induction without maintenance (6 instillations over 6 weeks) in remaining recurrence-free at 48 months (50% vs. 46%, p=0.26) or in risk of progression to MIBC (2.9% vs. 1.3%).<sup>234</sup> One trial (n=138) of patients with papillary NMIBC found no difference between epirubicin 40 mg induction therapy (6 instillations over 5 weeks) versus maintenance therapy (17 instillations over 1 year) in likelihood of remaining recurrence-free at 3 years (75% vs. 77%, p=0.62) or likelihood of progression (2.9% vs. 1.4%).<sup>229</sup> Both trials found no differences in risk of local adverse events.

Five trials compared different epirubicin regimens that included maintenance therapy.<sup>216,219,220,225,227</sup> One trial (n=269) of patients with multiple or recurrent Ta or T1 tumors or a solitary T1 tumor found no differences in likelihood of remaining recurrence- or progression-free at 5 years between epirubicin 50 mg administered as nine instillations over 6 months versus the same regimen plus an additional instillation within 48 hours of TURBT or the same regimen plus two additional maintenance instillations through 1 year.<sup>216</sup> One trial (n=150) of patients with Ta or T1 NMIBC (not selected for being at higher risk) found epirubicin 30 mg administered as 19 instillations over 1 year associated with lower risk of recurrence than nine instillations over 3 months (13% vs. 32%, HR 0.39, 95 % CI 0.18 to 0.82) after a median followup of 31 months.<sup>219</sup> A trial (n=125) of patients with Ta-T1/G1-G2 NMIBC found no difference between epirubicin 30 mg administered as 19 instillations over 1 year versus 12 instillations over 5 months in likelihood of remaining recurrence-free at 3 years (48% vs. 55%, p>0.05).<sup>227</sup> Another trial of patients with Ta-T1/G1-G2 NMIBC compared epirubicin 20 mg administered as 17 instillations over 12 months (total dose 340 mg), 30 mg given in 12 instillations over 7 months (total dose 360 mg), and 40 mg given in nine instillations over 4 months (total dose 360 mg).<sup>220</sup> The median time to recurrence was 688, 1007, and 1186 days, respectively (p=0.04 for dose/intensity response). There were no differences in mortality or bladder cancer mortality. A trial (n=69) of patients with Ta-T1/G1-G3 NMIBC compared four 12-week regimens involving epirubicin 30 mg that varied in the total dose administered (180 vs. 360 mg) and method of initiating therapy (once every 2 weeks starting 1 week after TURBT versus 3 instillations within the first 5-7 days after TURBT).<sup>225</sup> It found no difference between regimens based on the intensity of instillation, but the lower-dose regimens were associated with higher risk of recurrence at 12 months (42% vs. 29%, p=0.01). In all five trials, risk of local and systemic adverse events were similar across regimens.

## **Gemcitabine**

### **Comparisons of Different Instillation Regimens**

One small trial (n=32) of recurrent multiple Ta, G1 or G2 bladder cancers was too underpowered to determine if there were differences between gemcitabine 2000 mg once weekly

for 6 weeks, twice weekly for 3 weeks, or a single instillation in likelihood of experiencing a complete response (disappearance of marker lesion and no new tumor, 44% vs. 40% vs. 10%).<sup>157</sup>

## **Thiotepa**

### **Comparisons of Different Doses**

Two trials (reported in the same publication) compared different doses of thiotepa.<sup>140</sup> One trial (n=46) of patients with multifocal or recurrent NMIBC, or who had experienced a complete response to thiotepa, found no difference between maintenance therapy with thiotepa 30 mg versus 60 mg (once every 4 weeks for up to 2 years) in likelihood of being recurrence-free at 12 months (63% vs. 69%).<sup>140</sup> There were no differences in risk of adverse events. Another trial (n=95) of patients with incompletely resected NMIBC or CIS found no difference between thiotepa 30 mg versus 60 mg in likelihood of success (reduction in tumor or remission) following two courses of therapy (48% vs. 47%, RR 1.03, 95% CI 0.67 to 1.57).<sup>140</sup> There was no difference in risk of adverse events, though the lower-dose regimen was associated with a trend towards decreased risk of leukopenia (2.0% vs. 13%, RR 0.15, 95% CI 0.02 to 1.20).

## **Interferon Alpha-2b**

### **Comparisons of Different Doses**

Four trials compared different doses of intravesical interferon alpha-2b.<sup>136,203,217,221</sup> Two trials compared 100 MU versus 10 MU (once weekly for 10 or 12 weeks, then once monthly for a total of 1 year),<sup>203,217</sup> one trial compared 80, 50, and 40 MU (weekly for 12 weeks),<sup>221</sup> and one trial compared 80, 60, and 40 MU (once weekly for 2 months, then once every 2 weeks for 4 months, then once monthly).<sup>136</sup> One trial focused on patients with Tis lesions and the others included patients with Ta and T1 tumors.<sup>203</sup> Although the trials generally found higher doses of interferon alfa-2b associated with improved outcomes related to recurrence, progression, or resolution of bladder cancer marker lesions, most differences were not statistically significant, due to small sample sizes (n ranged from 24 to 89) with imprecise estimates. One trial found a statistically significant dose-dependent difference in recurrence rate with 80, 60, and 40 MU (1.19 vs. 0.88 vs. 0.63 per 100 patient-months, respectively).<sup>136</sup> The trial of patients with Tis found 100 MU associated with increased likelihood of a complete response (resolution of Tis, negative cytology, and no transitional cell carcinomas; 21% vs. 2.1% at 21 months, RR 10.0, 95% CI 1.33 to 75.0) and decreased risk of progression (13% vs. 37%, RR 0.35, 95% CI 0.15 to 0.82), with no difference in risk of cystectomy (15% vs. 18%, RR 0.81, 95% CI 0.31 to 2.10).<sup>203</sup> There were no clear differences in risk of local or systemic adverse events, including flu-like symptoms.<sup>136,203,217,221</sup>

## **Multiple Drugs**

One trial found no difference between initiation of intravesical therapy (9 instillations over 6 months) with MMC 30 mg or doxorubicin 50 mg on the day of TURBT versus 1 to 2 weeks after TURBT in risk of recurrence (43% vs. 49% after 2.75 years, p=0.18), progression to invasive bladder cancer (11% vs. 10%), or mortality (19% vs. 21%, p=0.60).<sup>212</sup> The trial also randomized patients after 6 months to maintenance therapy for an additional 6 months or no maintenance. It found no differences in risk of recurrence (43% vs. 50% after 3 years, p=0.20), progression (9% vs. 8%), or mortality (17% vs. 20%). However, in a multivariate model that adjusted for

prognostic factors, patients who received delayed therapy and no maintenance had a higher rate of recurrence than the other patients. Rates of local and systemic side effects were low, with no clear differences between regimens.

One trial of responders to 5-week induction therapy with sequential mitomycin and doxorubicin found maintenance therapy through 12 months associated with decreased risk of recurrence versus no maintenance therapy that was of borderline statistical significance (36% vs. 65%, RR 0.55, 95% CI 0.30 to 1.0).<sup>202</sup> The estimate for risk of progression was very imprecise (RR 3.12, 95% CI 0.35 to 28.0).

**Key Question 4.** For patients with high-risk non–muscle-invasive bladder cancer treated with TURBT, what is the effectiveness of external beam radiation therapy (either alone or with systemic chemotherapy/immunotherapy) for decreasing mortality or improving other outcomes compared with intravesical chemotherapy/immunotherapy alone or cystectomy?

## Key Points

- One randomized trial of patients with T1G3 bladder cancer found no effects of radiation therapy versus no radiotherapy (unifocal disease and no CIS) or radiation therapy versus intravesical therapy (multifocal disease or CIS) in recurrence-free survival (HR 0.94, 95% CI 0.67 to 1.30), progression-free interval (HR 1.07, 95% CI 0.65 to 1.74), progression-free survival (HR 1.35, 95% CI 0.92 to 1.98), or overall survival (HR 1.32, 95% CI 0.86 to 2.04) after 5 years (SOE: low).

## Detailed Synthesis

One randomized trial (rated medium risk of bias) compared external beam radiation therapy versus no radiation therapy in patients with NMIBC (Appendixes E5, F2).<sup>239</sup> Patients with T1G3 lesions and unifocal disease without CIS were randomized to radiation therapy (60 Gy in 30 fractions during 6 weeks or equivalent) versus no radiotherapy (group 1, n=77) and patients with multifocal disease or CIS were randomized to radiation therapy versus intravesical therapy (group 2, n=133). Radiation therapy was associated with no effects on recurrence-free survival (HR 0.94, 95% CI 0.67 to 1.30), progression-free interval (HR 1.07, 95% CI 0.65 to 1.74), progression-free survival (HR 1.35, 95% CI 0.92 to 1.98), or overall survival (HR 1.32, 95% CI 0.86 to 2.04) after 5 years. The rate of progression to muscle invasive disease was high (~32% overall). There was no evidence of an interaction between effects of radiotherapy and the patient group. Rates of cystectomy were similar (14% vs. 16%), and there was no clear difference in risk of long-term adverse events.

One cohort study of T1G3 patients found that patients who underwent radiotherapy plus TURBT had lower likelihood of progression than those who underwent TURBT alone, but there was no difference compared with TURBT + intravesical therapy, and the study did not attempt to adjust for potential confounders (Appendixes E5, F3).<sup>240</sup>

Key Question 5. In surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of various urinary biomarkers to decrease mortality or improve other outcomes compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging)?

### **Key Points**

- No study evaluated the effectiveness of urinary biomarkers to decrease mortality or improve other outcomes compared with standard diagnostic methods or other urinary biomarkers (SOE: insufficient).

### **Detailed Synthesis**

No study evaluated the effectiveness of urinary biomarkers to decrease mortality or improve other outcomes compared with standard diagnostic methods or other urinary biomarkers.

Key Question 5a. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers?

### **Key Points**

- No evidence (SOE: insufficient).

Key Question 5b. Does the comparative effectiveness differ according to the treatment used (i.e., specific chemotherapeutic or immunotherapeutic agents and/or TURBT)?

### **Key Points**

- No evidence (SOE: insufficient).

Key Question 5c. Does the comparative effectiveness differ according to the length of surveillance intervals?

### **Key Points**

- No evidence (SOE: insufficient).

Key Question 5d. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, or race/ethnicity?

### **Key Points**

- No evidence (SOE: insufficient).

**Key Question 6.** For initial diagnosis or surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of blue light or other methods of augmented cystoscopy compared with standard cystoscopy for recurrence rates, progression of bladder cancer, mortality, or other clinical outcomes?

## Key Points

- There was no difference between fluorescent versus white light cystoscopy in risk of mortality (3 trials, RR 1.28, 95% CI 0.55 to 2.95,  $I^2=41\%$ ) (SOE: low).
- Fluorescent cystoscopy with 5-ALA or hexaminolevulinate (HAL) was associated with decreased risk of bladder cancer recurrence versus white light cystoscopy at short-term (<3 months, 9 trials, RR 0.58, 95% CI 0.36 to 0.94,  $I^2=75\%$ ), intermediate-term (3 months to <1 year, 5 trials, RR 0.67, 95% CI 0.51 to 0.88,  $I^2=35\%$ ), and long-term followup ( $\geq 1$  year, 11 trials, RR 0.81, 95% CI 0.68 to 0.98,  $I^2=64\%$ ), but findings were inconsistent and potentially susceptible to performance bias (due to failure to blind the initial cystoscopy) and publication bias (SOE: low).
- There was no difference between fluorescent versus white light cystoscopy in risk of progression to muscle invasive bladder cancer (9 trials, RR 0.78, 95% CI 0.55 to 1.12,  $I^2=0\%$ ) (SOE: moderate).
- Narrow band imaging was associated with lower risk of bladder cancer recurrence at 3 months (3.9% vs. 17%, OR 0.62, 95% CI 0.41 to 0.92) and at 12 months (OR 0.24, 95% CI 0.07 to 0.81) in one trial (SOE: low).

## Detailed Synthesis

Fourteen trials (reported in 19 publications) evaluated clinical outcomes of augmented (fluorescent or narrow band imaging) cystoscopy versus standard white light cystoscopy (Table 19; Appendix E6).<sup>241-259</sup> Thirteen trials evaluated fluorescent cystoscopy following instillation of the photosensitizer 5-ALA, which is not commercially available (6 studies),<sup>241,246,252,256,257,259</sup> or HAL (7 studies).<sup>245,247,248,250,251,255,258</sup> One trial evaluated narrow band imaging.<sup>254</sup> Sample sizes ranged from 44 to 551 and duration of followup from 6 weeks to 60 months. Mean age of participants ranged from 60 to 70 years of age and participants were predominantly male, except in the trial of narrow band imaging (~80% female). One trial was conducted in the United States, Canada, and Europe;<sup>249,258</sup> the remainder were conducted in Europe. One trial restricted enrolment to patients with new bladder cancer;<sup>255</sup> the other trials included patients with either new or recurrent bladder cancer or did not specify whether patients had new or recurrent bladder cancer. In all studies, patients underwent TURBT and intravesical therapy protocols varied. Followup analyses were restricted to patients with NMIBC (Ta, T1, and in some cases CIS) on initial cystoscopy. Followup was performed with fluorescent light cystoscopy in one trial;<sup>256</sup> in the other trials followup was performed with white light cystoscopy or the method was not reported. Three trials were rated high risk of bias and the other 11 medium risk of bias (Appendix F2). Only one trial described an adequate randomization method,<sup>254</sup> four trials reported adequate allocation concealment,<sup>247,248,255,257</sup> and four trials reported followup cystoscopic examinations blinded to initial cystoscopy method.<sup>247,248,257,259</sup> All trials except for one used an unblinded design. It evaluated cystoscopic examination with white light and fluorescent cystoscopy blinded to instillation of fluorescent photosensitizer versus placebo,

which could reduce performance bias.<sup>259</sup> In one other trial, patients were initially randomized to no HAL versus HAL and all underwent white light cystoscopy; the HAL group subsequently underwent a second randomization to fluorescent cystoscopy versus no fluorescent cystoscopy.<sup>258</sup> Although this design may reduce performance bias related to performance of the initial white light cystoscopy, the second cystoscopic examination was still unblinded. Four trials reported high attrition<sup>252,257-259</sup> and one trial did not report attrition.

Fluorescent cystoscopy was associated with decreased risk of bladder cancer recurrence versus white light cystoscopy at short-term (<3 months, 9 trials, RR 0.58, 95% CI 0.36 to 0.94,  $I^2=75\%$ , Figure 34),<sup>241,245,247,248,251,252,255,256,259</sup> intermediate-term (3 months to <1 year, 5 trials, RR 0.67, 95% CI 0.51 to 0.88,  $I^2=35\%$ , Figure 35),<sup>245,248,250,256,258</sup> and long-term followup ( $\geq 1$  year, 11 trials, RR 0.81, 95% CI 0.68 to 0.98,  $I^2=64\%$ , Figure 36) (Table 20).<sup>241,245,246,248,250,251,255-259</sup> Estimates were similar in sensitivity analysis using the profile likelihood method.

Statistical heterogeneity was not reduced and estimates were similar when trials were stratified according to the photosensitizer used (5-ALA or HAL), risk of bias (medium or high), or masking of followup cystoscopy to the initial cystoscopy method. Results were also similar in an analysis restricted to recurrence assessed at around 1 year (9 to 16 months) (9 trials, RR 0.80, 95% CI 0.63 to 1.02,  $I^2=69\%$ ).<sup>241,245,248,250,251,255,257-259</sup> For short-term recurrence, two outlier trials reported point estimates that favored white light cystoscopy. One of the trials was the only one in which the initial cystoscopy was blinded to use of a photosensitizer (patients randomized to identical 5-ALA and placebo solutions and all underwent cystoscopy using fluorescent light) (RR 1.37, 95% CI 0.90 to 2.09).<sup>259</sup> It also reported an estimate that favored white-light cystoscopy for long-term recurrence (RR 1.20, 95% 0.94 to 1.52). The other trial was the only one that restricted inclusion to patients with new bladder cancer (RR 1.16, 95% CI 0.61 to 2.19).<sup>255</sup> Although all patients in this trial, including those with low-risk lesions, received single-shot intravesical MMC, other trials that reported more favorable effects of fluorescent cystoscopy on risk of recurrence also administered intravesical therapy in patients with low-risk lesions.<sup>241,245-247,256</sup>

One other trial (n=604) did not meet inclusion criteria because it was published only as an abstract, but also reported results inconsistent with overall pooled estimates.<sup>260</sup> It found no differences between fluorescent versus white light cystoscopy in risk for recurrence at short-term (29% vs. 29%) or long-term (24-month) followup (18% vs. 19%). Followup was performed with fluorescent cystoscopy.

There was no difference between fluorescent versus white light cystoscopy in risk of progression to muscle-invasive bladder cancer (9 trials, RR 0.78, 95% CI 0.55 to 1.12,  $I^2=0\%$ , Figure 37).<sup>241,245,246,248,251,256-259</sup> Estimates were similar in analyses stratified by the photosensitizer used, risk of bias, masking of the followup cystoscopy to the initial cystoscopy method, or duration of followup (9-18 months versus >24 months). Results were also similar when the one trial that performed followup using fluorescent cystoscopy was excluded.<sup>256</sup>

There was no difference between fluorescent versus white light cystoscopy in risk of mortality, though this outcome was only reported in three trials and the estimate was imprecise (RR 1.28, 95% CI 0.55 to 2.95,  $I^2=41\%$ , Figure 38).<sup>255,257,258</sup> Stratification by the photosensitizer used, the duration of followup, and risk of bias did not reduce statistical heterogeneity. There was also no difference between fluorescent versus white light cystoscopy in risk of mortality when the one trial<sup>256</sup> that performed followup using fluorescent cystoscopy was excluded, or when the analysis was performed using the profile likelihood method.

One trial evaluated outcomes following use of narrow band imaging versus white light cystoscopy. It found narrow band imaging associated with lower risk of bladder cancer recurrence at 3 months (3.9% vs. 17%, OR 0.62, 95% CI 0.41 to 0.92) and at 12 months (OR 0.24, 95% 0.07 to 0.81).<sup>254</sup> It did not report effects of narrow band imaging on risk of bladder cancer progression or mortality.

**Figure 34. Meta-analysis of fluorescent cystoscopy versus white light cystoscopy: Risk of bladder cancer recurrence at short term (<3 months) followup**

ALA = aminolevulinic acid; CI = confidence interval; HAL = hexaminolevulinate

**Figure 35. Meta-analysis of fluorescent cystoscopy versus white light cystoscopy: Risk of bladder cancer recurrence at intermediate term (3 months to <1 year)**

CI = confidence interval; HAL = hexaminolevulinate

**Figure 36. Meta-analysis of fluorescent cystoscopy versus white light cystoscopy: Risk of bladder cancer recurrence at long term ( $\geq 1$  year)**

ALA = aminolevulinic acid; CI = confidence interval; HAL = hexaminolevulinate

**Figure 37. Meta-analysis of fluorescent cystoscopy versus white light cystoscopy: Risk of progression to muscle-invasive bladder cancer**

ALA = aminolevulinic acid; CI = confidence interval; HAL = hexaminolevulinate

**Figure 38. Meta-analysis of fluorescent cystoscopy versus white light cystoscopy: Risk of mortality**

ALA = aminolevulinic acid; CI = confidence interval; HAL = hexaminolevulinate

**Key Question 7. What are the comparative adverse effects of various tests for diagnosis and post-treatment surveillance of bladder cancer, including urinary biomarkers, cytology, and cystoscopy?**

## Key Points

- Urinary biomarkers miss 23 to 42 percent of patients with bladder cancer and are incorrectly positive in 11 to 28 percent of patients without bladder cancer, but no study directly measured effects of inaccurate diagnosis on clinical outcomes (SOE: insufficient).
- There were no clear differences between fluorescent cystoscopy versus white light cystoscopy in risk of false-positives in two trials (SOE: low).
- There were no clear differences between fluorescent cystoscopy versus white light cystoscopy in risk of renal and genitourinary adverse events in two trials (SOE: low).

## Detailed Synthesis

Urinary biomarkers are associated with potential harms as a result of false-negative tests (which could result in a failure to perform cystoscopy and diagnosis bladder cancer when it is present) or false-positive tests (which could result in unnecessary cystoscopy when bladder cancer is absent). As presented in Key Question 1, the sensitivity of urinary biomarkers ranged from 0.58 to 0.77, meaning that 23 to 42 percent of cancers were missed, and the specificity ranged from 0.72 to 0.89, meaning that 11 to 28 percent of patients without bladder cancer had incorrectly positive tests. However, no study directly measured the clinical consequences of false-negative or false-positives in terms of clinical outcomes such as morbidity, mortality, quality of life due to delayed diagnosis, or complications related to unnecessary cystoscopy.

Harms were not well reported in 13 trials of fluorescent cystoscopy versus white light cystoscopy. Seven trials did not report adverse events at all; two others reported no complications associated with intravesical instillation of the photosensitizer HAL but did not describe methods used to identify adverse events.<sup>248,255</sup> Two trials found no clear difference in risk of false-positives with HAL fluorescent cystoscopy versus white light cystoscopy (25% vs. 16%, RR 1.51, 95% CI 0.88 to 2.57 and 10% vs. 12%, RR 0.80, 95% CI 0.62 to 1.04).<sup>250,258</sup> There were also no clear differences between fluorescent cystoscopy versus white light cystoscopy in risk of renal and genitourinary adverse events<sup>257,258</sup> or serious adverse events.<sup>258,259</sup> One trial found no difference between narrow band imaging versus white light cystoscopy in risk of false-positives.<sup>254</sup>

**Key Question 8. What are the comparative adverse effects of various treatments for non–muscle-invasive bladder cancer, including intravesical chemotherapeutic or immunotherapeutic agents and TURBT?**

## Key Points

### Intravesical Therapy Versus No Intravesical Therapy

- Four trials of BCG vs. no intravesical therapy reported granulomatous cystitis or irritative symptoms in 27 to 84 percent of patients, macroscopic hematuria in 21 to 72 percent, and fever in 27 to 44 percent. Harms were not reported in patients who did not receive intravesical therapy (SOE: low).
- Evidence on harms associated with non-BCG intravesical therapies versus no intravesical therapy was very limited, though some trials reported an increased risk of local adverse events. Evidence was insufficient to determine effects of non-BCG intravesical therapies versus no intravesical therapy on risk of systemic adverse events (SOE: low for local adverse events, insufficient for systemic adverse events).

### BCG Versus MMC

- BCG was associated with increased risk of any local adverse event (2 trials, RR 2.01, 95% CI 1.59 to 2.54,  $I^2=0\%$ ), granulomatous cystitis (5 trials, RR 1.71, 95% CI 1.22 to 2.41,  $I^2=58\%$ ), dysuria (3 trials, 48% vs. 32%, RR 1.23, 95% CI 1.03 to 1.46,  $I^2=34\%$ ), and hematuria (6 trials, RR 1.78, 95% CI 1.24 to 2.56,  $I^2=62\%$ ) versus MMC (SOE: low for local adverse events and dysuria; moderate for granulomatous cystitis and hematuria).

- BCG was associated with increased risk of any systemic adverse event (2 trials, RR 2.01, 95% CI 1.59 to 2.54,  $I^2=0\%$ ) and fever (4 trials, RR 4.51, 95% CI 2.31 to 8.82,  $I^2=25\%$ ) versus MMC (SOE: low for systemic adverse events and fever).
- There was no difference between BCG versus MMC in risk of discontinuation of instillations (4 trials, RR 1.26, 95% CI 0.39 to 4.01,  $I^2=70\%$ ) (SOE: low).
- BCG was associated with increased risk of discontinuation of instillations versus BCG plus MMC given sequentially (1 trial, RR 4.06, 95% CI 2.09 to 7.86) (SOE: low).

## **BCG Plus MMC Versus MMC**

- There was no difference between sequentially administered BCG plus MMC and MMC alone in local adverse events (1 trial, RR 1.36, 95% CI 0.60 to 3.08) or risk of cystitis (1 trial, RR 1.30, 95% CI 0.88 to 1.93) (SOE: low for local adverse events and cystitis).
- There was no difference between BCG and MMC given sequentially and MMC used alone in systemic adverse events (1 trial, RR 1.07, 95% CI 0.63 to 1.84) but BCG plus MMC was associated with increased risk of fever (1 trial, 12% vs. 3%, RR 3.75, 95% CI 1.08 to 13) (SOE: low for systemic adverse events and fever).
- There was no difference between alternating BCG plus MMC and MMC alone in risk of discontinuation of instillations in patients with CIS (1 trial, RR 0.54, 95% CI 0.16 to 1.84) or in patients with Ta or T1 tumors (1 trial, RR 0.93, 95% CI 0.52 to 1.65) (SOE: low).

## **BCG Versus Doxorubicin**

- BCG was associated with increased risk of cystitis versus doxorubicin (1 trial, RR 17, 95% CI 1 to 289), but there was insufficient evidence to determine effects on dysuria (3 trials, data not pooled) and hematuria (2 trials, data not pooled) due to small numbers of trials with inconsistent results (SOE: low for cystitis; insufficient for dysuria and hematuria).

## **BCG Versus Epirubicin**

- BCG was associated with increased risk of local side effects (1 trial, RR 3.28, 95% CI 1.26 to 8.53), granulomatous cystitis (4 trials, RR 1.86, 95% CI 1.35 to 2.56,  $I^2=65\%$ ), dysuria (1 trial, RR 2.43, 95% CI 1.13 to 5.24), hematuria (4 trials, RR 1.77, 95% CI 1.41 to 2.22,  $I^2=0\%$ ) and fever (2 trials, RR 9.73, 95% CI 2.72 to 35,  $I^2=0\%$ ) versus epirubicin alone, but results were mixed for discontinuation of intravesical therapy (2 trials, data not pooled) (SOE: low for local side effects, dysuria; granulomatous cystitis, hematuria, and fever; insufficient for discontinuation of instillations).
- BCG was associated with increased risk of systemic adverse events (1 trial, RR 5.97, 95% CI 2.18 to 16), granulomatous cystitis (1 trial, RR 2.28, 95% CI 1.46 to 3.54) and discontinuation of instillations (1 trial, RR 4.56, 95% CI 1.35 to 15) versus sequentially administered BCG and epirubicin, but there was no difference in risk of dysuria (1 trial, RR 1.22, 95% CI 0.56 to 2.66), hematuria (2 trials, RR 2.27, 95% CI 0.86 to 6.00,  $I^2=0\%$ ) or fever (2 trials, RR 2.09, 95% CI 0.48 to 9.02,  $I^2=0\%$ ) (SOE: low for systemic adverse events, granulomatous cystitis, discontinuation of instillations, dysuria, hematuria, and fever).

## **BCG Versus Gemcitabine**

- There were no differences between BCG and gemcitabine in risk of local adverse events requiring postponement or discontinuation of intravesical therapy (1 trial, RR 1.33, 95% CI 0.32 to 5.49), systemic adverse events (1 trial, RR 0.50, 95% CI 0.10 to 2.5), dysuria (2 trials, RR 1.51, 95% CI 0.92 to 2.50,  $I^2=0\%$ ), or hematuria (2 trials, RR 4.62, 95% CI 0.78 to 27,  $I^2=29\%$ ), but BCG was associated with increased risk of fever (2 trials, RR 6.24, 95% CI 1.03 to 38,  $I^2=5\%$ ) (SOE: low for local and systemic adverse events, dysuria, hematuria, and fever).
- One trial found no difference between BCG versus BCG plus gemcitabine given sequentially in risk of dysuria (RR 0.92, 95% CI 0.52 to 1.65) or hematuria (RR 0.30, 95% CI 0.08 to 1.09) (SOE: low).

## **BCG Versus Interferon**

- BCG was associated with increased risk of dysuria versus interferon alpha-2a (1 trial, RR 84, 95% CI 5.29 to 1319) but no difference in risk of fever (1 trial, RR 4.82, 95% CI 0.25 to 94) (SOE: low for dysuria and fever).
- BCG was associated with increased risk of constitutional symptoms (1 trial, RR 1.63, 95% CI 1.12 to 2.38) and fever (1 trial, RR 2.26, 95% CI 1.30 to 3.95) versus coadministration of BCG and interferon alpha-2b (SOE: low for constitutional symptoms and fever).

## **BCG Versus Thiotepa**

- BCG was associated with increased risk of bladder irritability (1 trial, RR 2.93, 95% CI 1.45 to 5.90), cystitis (1 trial, RR 18, 95% CI 1.11 to 306), and fever (1 trial, RR 8.36, 95% CI 0.47 to 150) versus thiotepa (SOE: low for dysuria, cystitis and fever).

## **MMC Versus Doxorubicin**

- Evidence was insufficient to determine effects of MMC versus doxorubicin on risk of local adverse events, based on inconsistent results from six trials (SOE: insufficient).

## **MMC Versus Epirubicin**

- One small trial found no difference between MMC versus epirubicin 80 mg in risk of urinary symptoms (SOE: low).

## **MMC Versus Interferon Alpha**

- One trial found MMC associated with greater risk of hematuria versus interferon alpha (RR 2.00, 95% CI 1.09 to 3.65), decreased risk of fever (RR 0.13, 95% CI 0.03 to 0.55), and no difference in risk of dysuria or urinary frequency (SOE: low).

## **MMC Versus Gemcitabine**

- One trial found MMC associated with increased risk of chemical cystitis versus gemcitabine (RR 3.93, 95% CI 1.17 to 13.14), with no difference in risk of dysuria or hematuria. (SOE: low).

## Doxorubicin Versus Epirubicin

- Doxorubicin was associated with increased risk of chemical cystitis versus epirubicin (1 trial, RR 1.85, 95% CI 1.13 to 3.03), with no clear difference in risk of dysuria or urinary frequency (2 trials) or hematuria (3 trials, RR 1.53, 95% CI 0.50 to 4.66,  $I^2=0\%$ ) (SOE: low for chemical cystitis, urinary frequency, and hematuria).

## Doxorubicin Versus Thiotepa

- One trial found no difference between doxorubicin versus thiotepa in risk of bladder irritability (RR 0.92, 95% CI 0.36 to 2.37) (SOE: low).

## Epirubicin Versus Interferon Alpha

- One trial found no difference between epirubicin versus interferon alpha in risk of dysuria or fever (SOE: low).

## Detailed Synthesis

### Intravesical Drugs Versus No Intravesical Therapy

Eight trials evaluated harms of intravesical therapy versus no intravesical therapy.<sup>117,131,133,135-138,140</sup> One trial evaluated MMC,<sup>117</sup> two trials epirubicin,<sup>131,133</sup> two trials interferon alpha,<sup>136,137</sup> one trial interferon-gamma,<sup>138</sup> one trial thiotepa,<sup>140</sup> and one trial gemcitabine.<sup>135</sup> Reporting of harms was suboptimal and focused primarily on local adverse events.

### BCG

Trials of BCG versus no intravesical therapy only reported harms in patients receiving BCG. Granulomatous cystitis or irritative vesical symptoms were reported in 27<sup>110</sup> to 84 percent<sup>104</sup> of patients, macroscopic hematuria in 21<sup>104</sup> to 72 percent,<sup>205</sup> and fever from 27<sup>104</sup> to 44 percent.<sup>109</sup>

### MMC

One trial (n=121) found no difference between a single instillation of MMC 40 mg versus TURBT alone in risk of chemical cystitis [3.5% (2/57) vs. 1.6% (1/64)].<sup>117</sup>

### Doxorubicin

No study evaluated harms of doxorubicin versus no intravesical therapy.

### Epirubicin

One trial found single instillation epirubicin 80 mg (up to 4 repeat instillations for recurrence) associated with increased risk of chemical cystitis versus placebo (12% vs. 1.9%; RR 6.29, 95% CI 2.22 to 17.8).<sup>131</sup> A second trial of single instillation epirubicin 100 mg versus no intravesical therapy also reported imprecise estimates and no statistically significant differences in risk of dysuria (5.9% [4/68] vs. 0.0% [0/66]; RR 8.74, 95% CI 0.48 to 159) or fever (0.0% [0/68] vs. 0.9% [1/66]; RR 0.32, 95% CI 0.01 to 7.80).<sup>133</sup>

## Gemcitabine

One trial (n=328) found no difference between a single instillation of gemcitabine 2000 mg versus placebo risk of experiencing at least one adverse event (30% vs. 26%; RR 1.11, 95% CI 0.79 to 1.57) or fever (1.2% [2/166] vs. 0.6% [1/162]).<sup>135</sup>

## Interferon Alpha

One trial (n=78) found no difference between interferon alpha versus no intravesical therapy in risk of urinary tract infection (23.3% vs. 16.7%, p=NS).<sup>137</sup> Another trial (n=89) of maintenance therapy with three different doses of interferon alpha (40, 60, and 80 MU) versus no intravesical therapy reported high fever related to urinary tract infections in five patients, but did not specify treatment groups.<sup>136</sup>

## Interferon Gamma

One trial (n=54) of induction therapy with interferon-gamma 21 MU (8 instillations over 8 weeks) versus no intravesical therapy reported no withdrawals from treatment due to adverse events, though harms were otherwise poorly reported.<sup>138</sup>

## Thiotepa

One trial (n=93) evaluated a maintenance regimen with thiotepa 60 or 30 mg versus no intravesical therapy.<sup>140</sup> Urinary tract symptoms were reported in 17 percent (4/23) of patients randomized to thiotepa 60 mg (2 patients with UTI and 2 with dysuria and urinary frequency) but no patients in the other groups (0% [0/23] vs. 0% [0/47]).<sup>140</sup>

## Intravesical Drugs Versus Intravesical Drugs

Fifteen trials evaluated harms of one drug administered for intravesical therapy versus another. Six trials evaluated MMC vs. doxorubicin,<sup>101,112,115,116,144,191</sup> one trial MMC vs. epirubicin,<sup>192</sup> two trials MMC vs. interferon alpha,<sup>193,221</sup> one trial MMC vs. gemcitabine,<sup>194</sup> three trials doxorubicin vs. epirubicin,<sup>119,195,196</sup> one trial doxorubicin vs. thiotepa,<sup>172</sup> and one trial epirubicin vs. interferon alpha.<sup>133</sup> Evaluation of harms was generally suboptimal and inconsistently reported.

## BCG Versus MMC

BCG was associated with increased risk of any local adverse event versus MMC when each was administered alone (2 trials, 40% vs. 20%, RR 2.01, 95% CI 1.59 to 2.54,  $I^2=0\%$ ).<sup>151,156</sup> Regarding specific local adverse events, BCG was also associated with increased risk of granulomatous cystitis (5 trials, 31% vs. 19%, RR 1.71, 95% CI 1.22 to 2.41,  $I^2=58\%$ ),<sup>111,153,155,156,160</sup> dysuria (3 trials, 48% vs. 32%, RR 1.23, 95% CI 1.03 to 1.46,  $I^2=34\%$ ),<sup>147,152,154</sup> and hematuria (36% vs. 18%, 6 trials, RR 1.78, 95% CI 1.24 to 2.56,  $I^2=62\%$ ).<sup>111,147,152-154,155</sup> Estimates were similar using the profile likelihood method. For granulomatous cystitis, excluding one trial<sup>160</sup> that administered nine instillations of MMC (versus 12 to 38 instillations in the other trials) reduced statistical heterogeneity, though the pooled estimate was similar (4 trials, RR 2.01, 95% CI 1.56 to 2.59,  $I^2=0\%$ ). Other sensitivity and subgroup analyses had little effect on findings.

BCG was also associated with increased risk of any systemic adverse event (3 trials, 14% vs. 4%, RR 2.93, 95% CI 1.80 to 4.78,  $I^2=0\%$ )<sup>151,156,160</sup> and fever (4 trials, 18% vs. 3%, RR 4.51, 95% CI 2.31 to 8.82,  $I^2=25\%$ ).<sup>147,152,153,155</sup>

There was no difference between BCG versus MMC alone in risk of discontinuation of further bladder instillations (4 trials, RR 1.26, 95% CI 0.39 to 4.01,  $I^2=70\%$ ), though statistical heterogeneity was present.<sup>149,152,153,160</sup> BCG was associated with reduced risk of discontinuation in one trial that did not include patients with grade 3 tumors, (4% vs. 24%, RR 0.18, 95% CI 0.04 to 0.78)<sup>153</sup> but was associated with increased risk of discontinuation in the three trials that included patients with grade 3 tumors (9% vs. 4%, RR 1.88, 95% CI 1.05 to 3.38,  $I^2=0\%$ ).<sup>149,152,160</sup>

No trial of BCG versus sequential BCG plus MMC evaluated risk of local or systemic adverse events. One trial (n=304) found BCG associated with increased risk of discontinuation of bladder instillations versus sequential BCG plus MMC (26% vs. 6%, RR 4.06, 95% CI 2.09 to 7.86)<sup>163</sup>

## BCG Plus MMC Versus MMC

One trial (n=182) found no difference between BCG plus MMC administered sequentially versus MMC alone in risk of experiencing any local adverse event (RR 1.36, 95% CI 0.60 to 3.08) or granulomatous cystitis (RR 1.30, 95% CI 0.88 to 1.93).<sup>166</sup> There was also no difference in risk of any systemic adverse event (1 trial, RR 1.07, 95% CI 0.63 to 1.84). Although BCG plus MMC was associated with increased risk of fever (1 trial, 12% vs. 3%, RR 3.75, 95% CI 1.08 to 13), the estimate was very imprecise.

One other trial (n=256) found no difference between alternating BCG plus MMC versus MMC alone in risk of discontinuation of intravesical therapy in patients with CIS (RR 0.54, 95% CI 0.16 to 1.84)<sup>169</sup> or in patients with Ta or T1 tumors (RR 0.93, 95% CI 0.52 to 1.65).<sup>168</sup>

## BCG Versus Doxorubicin

One trial found BCG associated with increased risk of cystitis versus doxorubicin, but the estimate was very imprecise (RR 17, 95% CI 1 to 289).<sup>172</sup> Findings for dysuria were mixed, with one trial finding decreased risk with BCG (RR 0.49, 95% CI 0.30 to 0.82),<sup>170</sup> one trial finding increased risk with BCG (RR 3.16, 95% CI 1.50 to 6.67),<sup>172</sup> and one trial finding no difference (RR 1.24, 95% CI 0.99 to 1.56).<sup>171</sup> The three trials differed in the dose of BCG (80 mg to 150 mg) and doxorubicin administered (20 mg to 50 mg). The trial that found BCG associated with decreased risk of dysuria used the lowest doses of both BCG and doxorubicin.

Effects on risk of systemic adverse events were also inconsistent. One trial found BCG associated with decreased risk of hematuria versus doxorubicin (RR 0.50, 95% CI 0.43 to 0.85),<sup>170</sup> but a second trial found no difference (RR 1.36, 95% CI 0.95 to 1.95).<sup>171</sup> One trial found BCG associated with increased risk of fever versus doxorubicin (RR 5.03, 95% CI 2.75 to 9.19),<sup>171</sup> but a second trial found no difference (RR 0.82, 95% CI 0.64 to 1.05).<sup>170</sup>

## BCG Versus Epirubicin

One trial found BCG associated with increased risk of any local side effect versus epirubicin when each was administered alone (20% vs. 6%, RR 3.28, 95% CI 1.26 to 8.53).<sup>177</sup> BCG was also associated with increased risk of granulomatous cystitis (4 trials, 48% vs. 28%, RR 1.86, 95% CI 1.35 to 2.56,  $I^2=65\%$ ),<sup>103,175,177,178</sup> dysuria (1 trial, 24% vs. 10%, RR 2.43, 95% CI 1.13 to 5.24),<sup>177</sup> and hematuria (4 trials, 33% vs. 19%, RR 1.77, 95% CI 1.41 to 2.22,  $I^2=0\%$ ).<sup>103,175,177,178</sup> For granulomatous cystitis, the estimate was similar using the profile likelihood method and subgroup analyses did not impact findings.

BCG was associated with increased risk of fever versus epirubicin when each was administered alone (2 trials, 16% vs. 1%, RR 9.73, 95% CI 2.72 to 35,  $I^2=0\%$ ).<sup>103,177</sup> One trial found BCG associated with increased risk of discontinuation of intravesical therapy (32% vs. 10%, RR 3.29, 95% CI 1.58 to 6.83),<sup>177</sup> though another trial found no difference (RR 0.95, 95% CI 0.85 to 1.05).<sup>178</sup>

BCG was associated with increased risk of granulomatous cystitis versus sequentially-administered BCG plus epirubicin (1 trial, 62% vs. 27%, RR 2.28, 95% CI 1.46 to 3.54),<sup>180</sup> but there was no difference in risk of dysuria (1 trial, RR 1.22, 95% CI 0.56 to 2.66)<sup>181</sup> or hematuria (2 trials, RR 2.27, 95% CI 0.86 to 6.00,  $I^2=0\%$ ).<sup>180,181</sup>

BCG was associated with increased risk of any systemic adverse event versus alternating BCG plus epirubicin (1 trial, 36% vs. 6%, RR 5.97, 95% CI 2.18 to 16),<sup>180</sup> but there was no difference in risk of fever (2 trials, RR 2.09, 95% CI 0.48 to 9.02,  $I^2=0\%$ ).<sup>180,181</sup> One trial found BCG associated with increased risk of discontinuation of intravesical therapy versus alternating BCG plus epirubicin (21% vs. 5%, RR 4.56, 95% CI 1.35 to 15).<sup>180</sup>

### **BCG Versus Epirubicin Plus Interferon**

One trial found BCG associated with increased likelihood of discontinuation of intravesical therapy versus the combination of epirubicin plus interferon, but the estimate was imprecise (9% vs. 2%, RR 5.41, 95% CI 1.23 to 24).<sup>182</sup> There was no difference in frequency of subjective urinary problems (specific adverse events and rates not reported).

### **BCG Versus Gemcitabine**

One trial found no difference between BCG versus gemcitabine in risk of local adverse events requiring postponement or discontinuation of intravesical therapy (RR 1.33, 95% CI 0.32 to 5.49).<sup>185</sup> Two trials found no difference between BCG versus gemcitabine in risk of dysuria (RR 1.51, 95% CI 0.92 to 2.50,  $I^2=0\%$ ) or hematuria (RR 4.62, 95% CI 0.78 to 27,  $I^2=29\%$ ).<sup>184,186</sup> No trial reported risk of granulomatous cystitis.

One trial found no difference between BCG versus gemcitabine in risk of any systemic adverse event (RR 0.50, 95% CI 0.10 to 2.5).<sup>185</sup> Two trials found BCG associated with increased risk of fever, though the estimate was imprecise (RR 6.24, 95% CI 1.03 to 38,  $I^2=5\%$ ).<sup>184,186</sup>

One trial found no difference between BCG versus BCG plus gemcitabine given sequentially in risk of dysuria (RR 0.92, 95% CI 0.52 to 1.65) or hematuria (RR 0.30, 95% CI 0.08 to 1.09).<sup>187</sup> No cases of fever were reported.<sup>187</sup>

### **BCG Versus Interferon**

One trial of BCG versus interferon alpha-2a found BCG associated with increased risk of dysuria (85% vs. 0%, RR 84, 95% CI 5.29 to 1319) and fever, but estimates were extremely imprecise (RR 4.82, 95% CI 0.25 to 94).<sup>188</sup>

One trial found BCG associated with increased risk of constitutional symptoms (18% vs. 11%, RR 1.63, 95% CI 1.12 to 2.38) and fever (11% vs. 5%, RR 2.26, 95% CI 1.30 to 3.95) versus BCG coadministered with interferon alpha-2b.<sup>190</sup>

### **BCG Versus Thiotepa**

One trial found BCG was associated with increased risk of bladder irritability (42% vs. 13%, RR 2.93, 95% CI 1.45 to 5.90), cystitis (16% vs. 0%, RR 18, 95% CI 1.11 to 306), and fever (7%

vs. 0%, RR 8.36, 95% CI 0.47 to 150) versus thiotepa.<sup>172</sup> No patient randomized to thiotepa reported cystitis or fever, resulting in very wide confidence intervals.

### **MMC Versus Doxorubicin**

Six trials reported inconsistent effects of MMC versus doxorubicin administered as induction or maintenance therapy in risk of dysuria or chemical cystitis.<sup>101,112,115,116,144,191</sup> Two trials found MMC was associated with decreased risk of chemical cystitis versus doxorubicin (8.9% vs. 22%, RR 0.41 [95% CI 0.22 to 0.75]<sup>116</sup> and 21% vs. 48%, RR 0.31 [95% CI 0.23 to 0.42]),<sup>191</sup> but one trial found MMC associated with a nonstatistically significant increased risk of chemical cystitis (19% vs. 13%, RR 1.44, 95% CI 0.32 to 6.54).<sup>144</sup> Three trials found no statistically significant differences in risk of dysuria or urinary frequency,<sup>112,115,116</sup> three trials found no difference in risk of hematuria,<sup>112,116,144</sup> and one trial found no difference in risk of bladder irritability.<sup>144</sup> Data were not poolable because event rates and sample sizes were not reported in all trials.

### **MMC Versus Epirubicin**

One small trial (n=44) found no difference between maintenance therapy with MMC 40 mg and a single instillation or maintenance therapy with epirubicin 80 mg in risk of urinary symptoms (13% [2/15] vs. 7% [1/14] vs. 13% [2/15], respectively).<sup>192</sup>

### **MMC Versus Interferon Alpha**

One trial (n=287) found induction therapy with MMC 40 mg associated with higher risk of hematuria versus interferon alpha (19% vs. 9.8%; RR 2.00, 95% CI 1.09 to 3.65).<sup>193</sup> There were no statistically significant differences in risk of dysuria (46% vs. 43%) or urinary frequency (47% vs. 41%). MMC was associated with lower risk of fever (1.4% vs. 11% ; RR 0.13, 95% CI 0.03 to 0.55). No patient in either group had to be withdrawn due to adverse effects. Another trial of induction regimens found no difference between MMC versus interferon alpha in risk of bladder pain (10% vs. 15%), though MMC was associated with increased risk of urinary frequency (28% vs. 11%, p not reported).<sup>221</sup> There were no clear differences in risk of withdrawal due to adverse events.

### **MMC Versus Interferon Gamma**

No study evaluated harms of MMC versus interferon-gamma.

### **MMC Versus Gemcitabine**

One trial (n=109) found induction therapy with MMC associated with increased risk of chemical cystitis versus gemcitabine (21% vs. 6%; RR 3.93, 95% CI 1.17 to 13.14).<sup>194</sup> There were no statistically significant differences in risk of dysuria (20% vs. 9%) or hematuria (7% vs. 4%). Treatment was delayed due to local adverse effects (not specified) in 10 percent of MMC patients and 5 percent of gemcitabine patients.

### **Doxorubicin Versus Epirubicin**

One trial found maintenance therapy with doxorubicin associated with increased risk of chemical cystitis versus epirubicin (35% vs. 19%; RR 1.85, 95% CI 1.13 to 3.03).<sup>119</sup> Three patients (5%) in the doxorubicin group experienced systemic side effects (one case each of thrombocytopenia, hypersensitivity reaction, and fever). Two trials of maintenance therapy

found no clear differences in risk of dysuria, or urinary frequency.<sup>195</sup> There was also no difference in risk of hematuria (3 trials, RR 1.53, 95% CI 0.50 to 4.66;  $I^2=0.0$ ).<sup>119,195,196</sup>

### Doxorubicin Versus Thiotepa

One trial (n=109) found no difference between maintenance therapy with doxorubicin versus thiotepa in risk of bladder irritability (13% vs. 14%; RR 0.92, 95% CI 0.36 to 2.37).<sup>172</sup> Other harms were not reported

### Epirubicin Versus Interferon Alpha

One trial (n=134) found no difference between a single instillation of epirubicin versus interferon alpha in risk of dysuria (5.9% [4/68] vs. 1.5% [1/66]) or fever (0.0% [0/68] vs. 6.1% [4/66]).<sup>133</sup> Other harms were not reported.

**Key Question 8a.** How do adverse effects of treatment vary by patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities such as chronic kidney disease?

### Key Points

- No study evaluated how harms of treatment vary in subgroups defined by patient characteristics such as age, sex, race/ethnicity, performance status, or medical comorbidities (SOE: insufficient).

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results**

Comparison	Author, Year	Population	Intervention	Results/Followup
BCG vs. MMC; BCG vs. MMC+BCG; BCG+MMC vs. MMC	DeBruyne, 1992 <sup>160</sup>  DeBruyne, 1988 <sup>150</sup> Witjes, 1998 <sup>159</sup>	Primary or recurrent superficial bladder cancer, including CIS, Ta, T1	A. BCG-RIVM (5 x 10 <sup>8</sup> CFU) in 50 mL saline weekly for 6 weeks  B. MMC 30 mg in 50 mL saline weekly for 4 weeks then monthly for 6 months	Recurrence: 42% vs. 36%  7 year followup: Recurrence 48% vs. 43% Progression 12% vs. 7% Mortality: 46 vs. 51 Malignant disease: 15 vs. 18  Median followup: 21 months
	Di Stassi, 2003 <sup>155</sup>	Histologically proven multifocal carcinoma in situ of the bladder and most had concurrent pT1 papillary transitional cell carcinoma	A. BCG 81 mg, 6 weekly instillations then monthly instillations for 10 months  B. MMC 40 mg, 6 weekly instillations then monthly instillations for 10 months  C. MMC 40 mg (electromotive), 6 weekly instillations then monthly instillations for 10 months	Overall mortality: 11/36 vs. 12/36 vs. 9/36 Recurrence: 19/36 vs. 27/36 vs. 19/36 Progression: 6/36 vs. 8/36 vs. 6/36 Granulomatous cystitis: 24/36 vs. 9/36 vs. 13/36 Fever: 7/36 vs. 0/36 vs. 0/36 Hematuria: 26/36 vs. 6/36 vs. 8/36  Median followup: 43 vs. 42 vs. 45 months
	Friedrich, 2007 <sup>154</sup>	Patients with primary transitional cell carcinoma of the bladder or tumor recurrence after TURBT without prior adjuvant therapy were eligible if pTaG1 tumor (size>3cm, recurrent or multifocal tumor) or pTaG2 up to pT1 tumor (G1-3). Patients with apT1G3 tumor were eligible in case of a unifocal small tumor (≤2.5 cm).	A. BCG RVIM, 6 weekly instillations  B. MMC 20 mg, 6 weekly instillations  C. MMC 20 mg, 6 weekly instillations followed by monthly instillations for 3 years	Recurrence: 41/163 vs. 46/179 vs. 16/153 Dysuria: 28/163 vs. 21/179 vs. 31/153 Hematuria: 19/163 vs. 1/179 vs. 14/153 Fever: 15/163 vs. 4/179 vs. 4/153  Median followup: 2.9 years

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Gardmark, 2007 <sup>157</sup> Lundholm, 1996 <sup>152</sup> Malmstrom, 1999 <sup>158</sup>	Stage Ta, grades 1 to 3 or stage T1, grades 1 and 2 tumors were included provided there had been at least 3 tumor events during the prior 18 months. Patients with stage T1 grade 3 and those with primary or concomitant dysplasia or carcinoma in situ were included without having had prior tumor events	A. BCG 120 mg, 6 weekly instillations followed by monthly instillations for 1 year then quarterly for 1 year  B. MMC 40 mg, 6 weekly instillations followed by monthly instillations for 1 year then quarterly for 1 year	Overall mortality: 68/125 vs. 72/125 Bladder cancer mortality: 19/125 vs. 26/125 Progression: 24/125 vs. 34/125 Fever: 29/125 vs. 7/125 DC instillations: 16/125 vs. 10/125 Dysuria: 100/125 vs. 87/125 Hematuria: 112/125 vs. 78/125  Median followup: 39 months; Also 10 year followup
	Gulpinar, 2012 <sup>162</sup>	Patients with intermediate or high risk for recurrence and progression according to the EAU guidelines were included. Patients with stage pTaG1 or pTaG2 tumors were included if tumor size > 3cm or recurrent or multifocal tumors. Patients with CIS, pTaG3 tumors and all pT1 tumors were included	A. BCG 5x10 <sup>8</sup> CFU, 6 weekly instillations beginning at least 15 days from TURBT  B. MMC 40, single dose at surgery followed by 6 weekly BCG instillations beginning at least 15 days from TURBT	Recurrence: 5/26 vs. 9/25 Progression: 1/26 vs. 1/25 Cystectomy: 1/26 vs. 1/25  Median followup: 41 months
	Jarvinen, 2009 <sup>161</sup> Rintala, 1991 <sup>149</sup>	Frequently recurrent TaT1 tumors and/or CISTa-T1 cancers with a minimum of two episodes of recurrence during the preceding 1.5 years	A. BCG 75 mg, 5 weekly instillations beginning 2 weeks after TURBT then monthly instillations for 2 years  B. MMC 30-40 mg, 5 weekly instillations beginning 2 weeks after TURBT then monthly instillations for 2 years	Overall mortality: 36/44 vs. 36/45 Bladder cancer mortality: 4/44 vs. 9/45 Recurrence: 26/44 vs. 36/45 Progression: 4/44 vs. 10/45 DC instillations: 10/44 vs. 5/45  Mean followup: 28 months; Also median followup 8.5 years

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Jarvinen, 2012 <sup>167</sup> Rintala, 1995 <sup>169</sup> (Jarvinen, 2012 <sup>167</sup> , Rintala, 1995 <sup>169</sup> and Rintala, 1996 <sup>168</sup> are part of same trial but results reported by subgroup)	Primary, secondary, or concomitant CIS	A. BCG 75 mg + MMC varied dose, 4 weekly instillations of MMC then MMC alternating with BCG monthly for 2 years  B. MMC varied dose, 4 weekly doses followed by monthly doses for two years	Overall mortality: 20/28 vs. 30/40 Bladder cancer mortality: 8/28 vs. 12/40 Recurrence: 19/28 vs. 35/40 Progression: 8/28 vs. 14/40 Cystectomy: 1/28 vs. 7/40  Mean followup: 33 months; Also median followup 7.2 years
	Kaasinen, 2003 <sup>163</sup>	High-grade primary, secondary, or concomitant (with pTa or pT1 tumor) carcinoma in situ of the urinary bladder	A. BCG 120 mg, 6 weekly instillations followed by monthly instillations up to one year  B. MMC 40 mg, 6 weekly instillations followed monthly alternating instillations with BCG for up to 1 year	Bladder cancer mortality: 10/145 vs. 13/159 Recurrence: 53/145 vs. 71/159 Progression: 20/145 vs. 34/159 Cystectomy: 4/145 vs. 4/159 DC instillations: 37/145 vs. 10/159  Median followup: 56 months
	Krege, 1996 <sup>111</sup>	Histological evidence of superficial bladder cancer (stage pTa/1 grades 1 to 3)	A. BCG 120 mg, 6 weekly instillation then monthly for 4 months  B. MMC 20 mg, instillations every 2 weeks for 1 year then monthly for 1 year	Recurrence: 26/102 vs. 30/112 Cystitis: 35/102 vs. 18/112 Cystectomy: 1/102 vs. 0/112 Fever: 18/102 vs. 0/112 Hematuria: 6/102 vs. 3/112  Mean followup: 20 months
	Lamm, 1995 <sup>147</sup>	Histologically proven, completely resected Ta (noninvasive) or T1 (lamina propria invasive) transitional cell carcinoma and at increased risk for tumor recurrence (2 occurrences of tumor within 56 weeks, stage T1 within 16 weeks of registration, or 3 or more tumors presenting simultaneously within 16 weeks)	A. BCG 50 mg, 6 weekly instillations then at 8 and 12 weeks, then monthly up to 1 year  B. MMC 20 mg, 6 weekly instillations then at 8 and 12 weeks, then monthly up to 1 year	Overall mortality: 25/191 vs. 28/186 Bladder cancer mortality: 8/191 vs. 12/186 Recurrence: 77/191 vs. 101/186 Progression: 15/191 vs. 24/191 Fever: 38/222 vs. 8/220 Dysuria: 115/222 vs. 80/222 Hematuria: 85/222 vs. 57/220  Median followup: 913 days

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Mangiarotti, 2008 <sup>153</sup>	Nonmuscle invasive bladder cancer not previously treated with any chemotherapeutic or immunotherapeutic agent	A. BCG 50 mg, 6 weekly instillations then monthly for up to 1 year  B. MMC 40 mg, 8 weekly instillations then monthly for up to 1 year	Overall mortality: 1/46 vs. 0/46 Recurrence: 23/46 vs. 23/46 Granulomatous cystitis: 16/46 vs. 10/46 Fever: 2/46 vs. 2/46 DC instillations: 2/46 vs. 11/46 Hematuria: 0/46 vs. 2/46  Mean followup: 66 months
	Mohsen, 2010 <sup>165</sup>	At least 2 histologically verified recurrent stage Ta or T1 during the preceding 1.5 years	A. BCG 5x10 <sup>8</sup> CFU, 6 weekly instillations 1 month after TURBT, then monthly for months 3-12  B. MMC 40 mg perioperatively, then 4 weekly instillations, then BCG monthly for months 2-13	Recurrence: 16/27 vs. 9/29 Cystectomy: 2/27 vs. 1/29  Mean followup: 24 months
	Ojea, 2007 <sup>151</sup>	Intermediate risk with stages TaG2 and T1G1-2 superficial bladder tumors without carcinoma in situ	A. BCG 27 mg, 6 weekly instillations then 6 biweekly instillations  B. BCG 13.5 mg, 6 weekly instillations then 6 biweekly instillations  C. MMC 30 mg, 6 weekly instillations then 6 biweekly instillations	A vs. B vs. C Overall mortality: 13/142 vs. 17/139 vs. 27/149 Bladder cancer mortality: 3/142 vs. 5/139 vs. 7/149 Recurrence: 38/142 vs. 50/139 vs. 58/149 Progression: 14/142 vs. 18/139 vs. 14/149 Local side effects: 93/142 vs. 9/139 vs. 45/149 Systemic side effects: 16/142 vs. 15/139 vs. 7/149  Median followup: 57 vs. 61 vs. 53 months

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Oosterlinck, 2011 <sup>164</sup>	Primary, concurrent, or recurrent biopsy-proven CIS	<p>A. BCG 5x10<sup>8</sup> CFU, 6 weekly instillations, then 3 weeks rest, then 3 weekly instillations, then 3 weekly instillations every 6 months up to 3 years</p> <p>B. MMC 40 mg, 6 weekly instillations then 6 weekly instillations of BCG then 3 weekly instillations (one MMC then 2 BCG) every 6 months up to 3 years</p>	<p>Overall mortality: 11/48 vs. 7/48 Bladder cancer mortality: 6/48 vs. 3/48 Recurrence: 26/48 vs. 23/48 Progression: 5/48 vs. 2/48 Cystectomy: 5/48 vs. 8/48</p> <p>Median followup: 4.7 years</p>
	Rintala, 1996 <sup>168</sup> (Jarvinen, 2012 <sup>167</sup> , Rintala, 1995 <sup>169</sup> and Rintala, 1996 <sup>168</sup> are part of same trial but results reported by subgroup	recurrent stage Ta or T1 papillary transitional cell carcinoma; no CIS	<p>4 weekly instillation of MMC then:</p> <p>A. BCG 5x10<sup>8</sup> CFU + MMC 40 mg (alternating monthly) for two years</p> <p>B. MMC 40 monthly for two years</p>	<p>Recurrence: 57/92 vs. 58/90 DC instillations: 18/92 vs. 19/90</p> <p>Mean followup: 34 months</p>

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Sekine, 2001 <sup>145</sup>	Tis with or without T1 bladder cancer	A: BCG, type of BCG, dose, and number and timing of instillations not reported  B: MMC, 20 mg and doxorubicin, 30 mg sequential therapy, number and timing of instillations not reported	Complete response to initial therapy (no residual CIS and negative urine cytology for at least 4 weeks): 86% (18/21) vs. 81% (17/21), RR 1.06 (95% CI 0.81 to 1.39) within 2 months of completion of therapy  Complete response, including crossover therapy: 90% (19/21) vs. 100% (21/21), RR 0.90 (95% CI 0.79 to 1.04)  Recurrence after complete response: 11% (2/21) vs. 52% (11/21), RR 0.18 (95% CI 0.05 to 0.72)  Progression: 14% (3/21) vs. 10% (2/21), RR 1.50 (95% CI 0.28 to 8.08)  Bladder cancer mortality: 10% (2/19) vs. 4.8% (1/21), RR 2.21 (95% CI 0.22 to 22.5)  Duration of followup: 47 months (range 3 to 143 months)  Method of followup: cystoscopy and urine cytology every 3 months and urography every 12 months
	Witjes, 1996 <sup>156</sup> Witjes, 1993 <sup>148</sup> Vegt, 1995 <sup>211</sup>	Histologically proven papillary pTa-pT1 transitional cell carcinoma of the bladder with or without CIS	A. BCG TICE 5x10 <sup>8</sup> CFU, 6 weekly instillations with a  B. BCG RIVM 5x10 <sup>8</sup> , 6 weekly instillations  C. MMC 30 mg, 4 weekly instillations then monthly for 5 months  If recurrence then additional instillations in all groups	A vs. B vs. C Recurrence: 75/117 vs. 62/134 vs. 58/136 Progression: 7/117 vs. 8/134 vs. 8/136 Granulomatous cystitis: 38/140 vs. 34/149 vs. 27/148 Local side effects: 23/140 vs. 22/149 vs. 7/148 Systemic side effects: 38/140 vs. 27/149 vs. 6/148  Median followup: 32 months

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Witjes, 1998b <sup>166</sup>	Histologically proved primary multiple (more than 2 tumors) or recurrent multiple (2 or more tumors) stage pTa or pT1 transitional cell carcinoma, solitary or multiple grade III tumors and primary or concomitant CIS	A. BCG 5x10 <sup>8</sup> CFU + MMC 40 mg, 4 weekly instillations of MMC then 6 weekly instillations of BCG  B. MMC 40, 10 weekly instillations	Overall mortality: 21/90 vs. 14/92 Bladder cancer mortality: 5/90 vs. 8/92 Recurrence: 35/90 vs. 42/92 Progression: 5/90 vs. 4/92 Local side effects: 12/90 vs. 9/92 Granulomatous cystitis: 37/90 vs. 29/92 Systemic side effects: 21/90 vs. 20/92 Fever: 11/90 vs. 3/92  Median followup: 32 months
<i>BCG vs. Epirubicin;</i> <i>BCG vs. Epirubicin + BCG</i>	Ali-El-Dein, 1999 <sup>180</sup>	Grade 2 or 3, stage pT1 disease, rapid disease recurrence within 6 months of initial resection, multicentricity, aneuploid DNA pattern, tumor size equal to or not more than 3 cm, assoc carcinoma in situ or other dysplastic mucosal changes and/or positive postoperative urinary cytology	A. BCG 5x10 <sup>8</sup> -5x10 <sup>9</sup> CFU, 6 weekly then 10 monthly instillations  B. Epirubicin 50 mg + BCG 5x10 <sup>8</sup> -5x10 <sup>9</sup> CFU, 6 weekly then 10 monthly instillations alternating BCG and epirubicin	Recurrence: 12/58 vs. 7/66 Progression: 5/58 vs. 3/66 Granulomatous cystitis: 36/58 vs. 18/66 Hematuria: 4/58 vs. 0/66 Fever: 3/58 vs. 0/66 DC instillations: 12/58 vs. 3/66 Systemic side effects: 21/58 vs. 4/66  Mean followup: 30 months
	Bilen, 2000 <sup>181</sup>	Superficial transitional-cell carcinoma of the bladder; patients with pT1 who had an additional one of four prognostic factors (grade 3 tumors, multiple tumors, tumors greater than 40 mm, recurrent tumors) were included	A. BCG 81 mg, 6 weekly instillations  B. Epirubicin 50 mg + BCG 81 mg, epirubicin given weeks 1-4 and week 12 and BCG given weeks 5-7, and 9-11	Recurrence: 4/21 vs. 3/20 Progression: 2/21 vs. 1/20 Hematuria: 8/21 vs. 4/20 Fever: 3/21 vs. 2/20 Dysuria: 9/21 vs. 7/20  Median followup: 18 months

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Cai, 2008 <sup>179</sup>	High risk NMIBC patients with recurrent urothelial cancer and with tumor recurrence at same stage and grade of the initial tumor at diagnosis	A. BCG 5x10 <sup>8</sup> CFU, 6 weekly instillations with boosters at 3, 6, 12, 18, 24, 30, and 36 months  B. Epirubicin 80 mg + BCG 5x10 <sup>8</sup> CFU, epirubicin given perioperatively then 6 weekly instillations of BCG with BCG boosters 3, 6, 12, 18, 24, 30, and 36 months	Recurrence: 40/81 vs. 34/80 Progression: 4/81 vs. 2/80  Median followup: 15 months
	Cheng, 2005 <sup>174</sup>	Superficial bladder cancer (Ta or T1) with one or more of the following: stage>a, grade>1size>1cm or multiple or recurrent tumors	A. BCG 81 mg, 6 weekly instillations then 10 monthly instillations  B. Epirubicin 50 mg, 4 weekly instillations then 5 monthly instillation then quarterly for 6 months	Overall mortality: 41/102 vs. 41/107 Bladder cancer mortality: 13/102 vs. 7/107 Recurrence: 30/102 vs. 59/107 Progression: 16/102 vs. 16/107  Median followup: 23 months for recurrence, 47 months for progression, 61 months for survival
	De Reijke, 2005 <sup>177</sup>	Patients with biopsy proven primary, secondary or concurrent CIS of the bladder with or without primary urinary cytology.	A. BCG 81 mg, 6 weekly instillations then at months 3, 6, 12, 18, 24, 30, 36  B. Epirubicin 50 mg, 8 weekly instillations then at months 3, 6, 12, 18, 24, 30, 36	Overall mortality: 26/84 vs. 34/84 Bladder cancer mortality: 9/84 vs. 13/84 Granulomatous cystitis: 21/80 vs. 7/82 Hematuria: 33/80 vs. 23/82 Fever: 6/80 vs. 0/82 DC instillations: 26/81 vs. 8/82 Local side effects: 16/80 vs. 5/82 Dysuria: 19/80 vs. 8/82  Median followup: 67 months
	Melekos, 1993 <sup>103</sup>	Histologically proven superficial transitional cell carcinoma of the bladder; primary or recurrent neoplasms	A. BCG 150 mg, 6 weekly instillations then quarterly for 2 years then semi-annually  B. Epirubicin 50 mg, 6 weekly instillations then quarterly for 2 years then semi-annually	Recurrence: 20/62 vs. 27/67 Progression: 4/62 vs. 6/67 Granulomatous cystitis: 49/62 vs. 23/67 Hematuria: 14/62 vs. 10/67 Fever: 17/62 vs. 2/67  Total months of followup: 1784 vs. 1745 months

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Melekos, 1996 <sup>175</sup>	Completely resectable recurrent (at least 2 recurrences in the most recent 12 months) or multiple (more than 2) papillary superficial bladder tumors Ta and T1 of any grade	A. BCG 5x10 <sup>8</sup> CFU, 6 weekly instillations then quarterly for 2 years then semiannually (if T1 or TaG2/G3 then 3 weekly doses at 6 months)  B. Epirubicin 50 mg, 4 weekly instillations then quarterly for 2 years then semiannually (if T1 or TaG2/G3 then 3 weekly doses at 3 and 6 months)	Recurrence: 26/58 vs. 34/61 Progression: 7/58 vs. 10/61 Granulomatous cystitis: 39/58 vs. 23/61 Hematuria: 14/58 vs. 10/61  Median followup: 43 months
	Hinotsu, 2011 <sup>176</sup>	Recurrent or multiple tumors with confirmed Ta or T1 transitional cell carcinoma; must have 1 of the following: (a) at least 3 tumors (b) recurrence is at least the third such event or (c) recurrence diagnosed within 12 months from previous TURBT for NMIBC	A. BCG 81 mg, 6 weekly instillations then 3 weekly instillations at months 3, 6, 12 and 18  B. BCG 81 mg, 6 weekly instillations  B. Epirubicin 40 mg, 2 weekly instillations then biweekly times 7	A vs. B vs. C* Recurrence: 5/41 vs. 14/42 vs. 22/32 Progression: 0/41 vs. 3/42 vs. 7/32  *groups A and B combined in analysis  Median followup: 2 years
	Sylvester, 2010 <sup>173</sup> Van Der Meijden, 2001 <sup>178</sup>	Intermediate or high risk superficial bladder tumors; single or multiple, primary or recurrent, completely resectable stages Ta-T1, G1 to G3, biopsy proven TCC	A. BCG 5x10 <sup>8</sup> CFU, 6 weekly instillations then 3 weekly instillations at months 3, 6, 12, 18, 24, 30 and 36  B. Epirubicin 50 mg, 6 weekly instillations then 3 weekly instillations at months 3, 6, 12, 18, 24, 30 and 36	Overall mortality: 84/281 vs. 106/173 Bladder cancer mortality: 41/102 vs. 41/107 Recurrence: 103/281 vs. 147/173 Progression: 19/281 vs. 24/173 Granulomatous cystitis: 111/263 vs. 82/265 Hematuria: 93/263 vs. 45/264 DC instillations: 190/265 vs. 201/265  Median followup: 4 years; Also median followup 9 years

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
<i>BCG vs. Gemcitabine;</i> <i>BCG vs. BCG + Gemcitabine</i>	Cho, 2009 <sup>187</sup>	Patients with intermediate-risk (i.e., Ta, T1, G1-G2 multifocal, recurrent lesions >3 cm, or high-risk (T1, G3 lesions or CIS) were included	A. BCG 12.5 mg, 6 weekly instillations  B. Gemcitabine 1000 mg first dose then 2000 mg at week 1, then BCG weekly for 6 weeks	Recurrence: 17/51 vs. 14/36 Progression: 5/51 vs. 3/36 Dysuria: 17/51 vs. 13/36 Hematuria: 3/51 vs. 7/36  Mean followup: 32 and 34 months
	Di Lorenzo, 2010 <sup>184</sup>	Patients with high risk NMIBC based on the European Organization for Research and Treatment of Cancer Scoring System failing BCG therapy for whom radical cystectomy was indicated but not conducted because of refusal or ineligibility because of age or comorbidities and high anesthesiological risk	A. BCG 81 mg, 6 weekly instillations then 3 weekly instillations at 3, 6 and 12 months  B. Gemcitabine 2000 mg twice weekly for 6 weeks then 3 weekly instillations at 3, 6 and 12 months	Overall mortality: 1/35 vs. 0/21 Recurrence: 35/40 vs. 21/40 Progression: 13/35 vs. 7/21 Dysuria: 8/40 vs. 6/40 Hematuria: 5/40 vs. 2/40 Fever: 3/40 vs. 1/40  Median followup: 15 months
	Gontero, 2013 <sup>186</sup>	Intermediate risk NMIBC (namely Ta-1, G1-2, multifocal or unique and recurrent, more than 3 cm in diameter) were eligible	A. BCG 27 mg, 6 weekly instillations then 3 weekly instillations at 3, 6 and 12 months  B. Gemcitabine 2000 mg, 6 weekly instillations then monthly instillations up to 1 year	Recurrence: 14/47 vs. 16/41 Progression: 3/47 vs. 5/41 Dysuria: 21/57 vs. 13/56 Hematuria: 9/57 vs. 0/56 Fever: 10/57 vs. 0/56  Followup 1 year
	Porena, 2010 <sup>185</sup>	Superficial TCC; high risk superficial bladder cancer according to EAU guidelines	A. BCG 5x10 <sup>8</sup> CFU, 6 weekly instillations then instillations at 3, 6, 12, 18, 24, 30 and 36 months  B. Gemcitabine 2000 mg, 6 weekly instillations then instillations at 3, 6, 12, 18, 24, 30 and 36 months	Recurrence: 9/32 vs. 17/32 Local toxicity: 4/32 vs. 3/32 Systemic toxicity: 2/32 vs. 4/32  Mean followup: 44 months

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
<i>BCG vs. Interferon alpha-2a; BCG vs. Interferon alpha-2b + BCG</i>	Jimenez-Cruz, 1997 <sup>188</sup>	Recurrent histologically proved superficial transitional cell carcinoma of the bladder (Stage T1, grade 1 to 3)	A. BCG 150 mg, 4 weekly instillations then biweekly for 2 months then monthly for 9 months  B. Interferon alpha-2a 54 MU, 4 weekly instillations then biweekly for 2 months then monthly for 9 months	Recurrence: 24/61 vs. 34/49 Progression: 6/61 vs. 7/49 Dysuria: 52/61 vs. 0/49 Fever: 3/61 vs. 0/49 Cystectomy: 3/61 vs. 0/49  Mean followup: 21 vs. 18 months
	Kaasinen, 2000 <sup>189</sup>	At least 2 histologically verified recurrent stage Ta or T1 grade 1 to 2 tumors without concomitant CIS, Grade 3 tumors also included	All patients received 5 instillations of MMC 40 mg prior to randomization  A. BCG 5x10 <sup>8</sup> CFU, 12 monthly instillations  B. Interferon alpha-2b 50 MU + BCG 5x10 <sup>8</sup> CFU, 12 monthly instillations (alternating drugs)	Recurrence: 29/102 vs. 70/103 Progression: 3/102 vs. 4/103  Median followup: 56 months
	Nepple, 2010 <sup>190</sup>	Histologically confirmed CIS, Ta, T1 urothelial cancer diagnosed within 8 weeks	A. BCG 50 mg then BCG 16.6 mg, 6 weekly instillations then 3 weekly instillations of BCG 16.6 mg at 4, 7, 13, 19, 25 and 37 months  B. Interferon alpha-2b 50 MU + BCG 16.6 mg, 6 weekly instillations then 3 weekly instillations of BCG 16.6 mg at 4, 7, 13, 19, 25 and 37 months  (Patients were also randomized to regular or mega-dose vitamins.)	Recurrence: 104/324 vs. 127/346 Constitutional symptoms: 58/324 vs. 38/346 Fever: 36/324 vs. 17/346  Followup 24 months

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
<i>BCG vs. Doxorubicin</i>	Hinotsu, 2006 <sup>170</sup>	Histopathologically proven transitional cell carcinoma (Stage pTa or pT1 and grade 1 to 2)	A. BCG 80 mg, 6 weekly instillations  B. Doxorubicin 20 mg, 2 weekly instillations then 7 biweekly followed by 8 monthly instillations	DC instillations: 1/41 vs. 2/42 Hematuria: 20/41 vs. 34/42 Fever: 28/41 vs. 35/42 Dysuria: 13/41 vs. 27/42  Median followup: 667 days
	Lamm, 1991 <sup>171</sup>	Transitional-cell carcinoma with tumors at stage Ta or T1 of any grade with two or more recurrences in the most recent 12 months, CIS, or both	A. BCG 120 mg, 6 weekly instillations then single instillations at 3, 6, 12, 16 and 24 months  B. Doxorubicin 50 mg, 4 weekly instillations then 11 monthly instillations	Overall mortality: 45/127 vs. 48/135 Recurrence: 78/127 vs. 110/135 Hematuria: 46/127 vs. 36/135 Fever: 52/127 vs. 11/135 Dysuria: 76/127 vs. 65/135
	Martinez-Pineiro, 1990 <sup>172</sup>	Histologically proved superficial transitional cell carcinoma; Initially Ta or T1 tumors admitted, later only T1 cancer patients admitted	A. BCG 150 mg, 4 weekly instillations then 11 monthly instillations  B. Doxorubicin 50 mg, 4 weekly instillations then 11 monthly instillations	Overall mortality: 0/67 vs. 1/53 Bladder cancer mortality: 0/67 vs. 1/53 Recurrence: 9/67 vs. 23/53 Progression: 1/67 vs. 4/53 Dysuria: 28/67 vs. 7/53 Cystectomy: 1/67 vs. 3/53 Cystitis: 11/67 vs. 0/53  Median followup: 3 years
<i>BCG vs. Thiotepa</i>	Brosman, 1982 <sup>142</sup>	NMIBC patients with at least one tumor recurrence within the preceding four months	A: BCG: 6 x 10 <sup>9</sup> TICE BCG in 60mL saline  B: Thiotepa: 60mg in 60mL saline  Both treatment groups were treated with weekly x 6 instillations, every 2 weeks for 3 months, then monthly until a total treatment period of 24 months.	Recurrence: 0/39 (includes 12 nonrandomized patients) vs. 9/19 (47%)  Minimum followup: 24 months

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Martinez-Pineiro, 1990 <sup>172</sup>	Histologically proved superficial transitional cell carcinoma; Initially Ta or T1 tumors admitted, later only T1 cancer patients admitted	A. BCG 150 mg, 4 weekly instillations then 11 monthly instillations  B. Doxorubicin 50 mg, 4 weekly instillations then 11 monthly instillations	Overall mortality: 0/67 vs. 1/56 Bladder cancer mortality: 0/67 vs. 0/56 Recurrence: 9/67 vs. 20/56 Progression: 1/67 vs. 2/56 Dysuria: 28/67 vs. 8/56 Cystectomy: 1/67 vs. 0/56 Cystitis: 11/67 vs. 0/56  Median followup: 3 years
<i>BCG vs. Epirubicin + Interferon alpha-2b</i>	Duchek, 2010 <sup>182</sup> Hemdan, 2014 <sup>183</sup>	Patients with newly detected T1 G2-G3 urinary bladder cancer	A. BCG 2 mL OncoTice, 6 weekly instillations then 3 weekly instillations at 3, 6, 12, 18 and 24 months  B. Epirubicin 50 mg + Interferon alpha-2b 10 MU, 6 weekly instillations then monthly at months 3-12 then at months 15, 18, 21 and 24	Disease-free survival favors BCG at 6 and 24 months (p=0.065; p=0.012, respectively) Bladder cancer mortality: 8/126 vs. 10/124 5-year Recurrence: 50/126 vs. 75/124 No difference in progression-free survival (p=not reported) Cystectomy: 9/126 vs. 13/124 DC instillations: 11/126 vs. 2/124 No difference in urinary symptoms (p=not reported)  Followup 24 months; Also median followup 6.9 years
<i>BCG vs. No intravesical therapy</i>	Herr, 1995 <sup>102</sup> Herr, 1988 <sup>106</sup> Herr, 1997 <sup>107</sup> Cookson, 1997 <sup>108</sup> Pinsky, 1985 <sup>109</sup>	Recurrent, superficial transitional-cell carcinoma of the bladder (Ta, T1, Tis)	A. BCG 120 mg, 6 weekly instillations  B. Control	Bladder cancer mortality: 10/43 vs. 17/45 Progression: 23/43 vs. 41/43 Cystectomy: 11/43 vs. 18/43  Median followup: 72 months; Also median followup: 108 vs. 140 months
	Melekos, 1990 <sup>104</sup>	Superficial bladder carcinoma (Ta and T1)	A. BCG 150 mg, 8 weekly instillations then every 3 months for 24 months  B. Control	Recurrence: 22/67 vs. 19/33 Progression: 7/67 vs. 13/33  Mean followup: 29 vs. 30 months
	Melekos, 1993 <sup>103</sup>	Histologically proven superficial transitional cell carcinoma of the bladder; primary or recurrent neoplasms	A. BCG 150 mg, 6 weekly instillations then quarterly for 2 years then semi-annually  B. Control	Recurrence: 20/62 vs. 19/32 Progression: 4/62 vs. 7/32  Total months of followup: 1784 vs. 603

**Table 6. Summary of bacillus Calmette-Guérin study characteristics and results (continued)**

Comparison	Author, Year	Population	Intervention	Results/Followup
	Pagano, 1991 <sup>105</sup> Pagano, 1990 <sup>110</sup>	Patients followed for one year after the study or until recurrence or progression were included in the report. Multiple (>3 tumors at entry), superficial papillary and nonpapillary tumors	A. BCG 75 mg, 6 weekly instillations then monthly for 1 year then quarterly for 1 year  B. Control	Progression: 3/70 vs. 11/63  Mean followup: 21 months

BCG = bacillus Calmette-Guérin; BCG (RIVM) = RIVM strain of bacillus Calmette-Guérin; CFU = colony forming unit; CIS = carcinoma in situ; DC = dendritic cells; EAU = European Association of Urology ; FISH = fluorescence in situ hybridization; FU = followup; G1 = Grade 1; G2 = Grade 2; G3 = Grade 3; MMC = Mitomycin C; MU = million units; NMIBC = non-muscle-invasive bladder cancer; NMP22 = nuclear matrix protein-22; pT1 = Tumor stage 1 determined by pathology; pTa = Tumor stage a determined by pathology; T1 = Tumor stage 1; Ta = Tumor stage a; TCC = transitional cell carcinoma; Tis = carcinoma in situ; TURBT = transurethral resection of bladder tumor

**Table 7. Summary of MMC study characteristics**

Author, Year	Setting and Study Years	Interventions (number analyzed for recurrence)	Duration of Followup and Method	Population Characteristics by Treatment Group (age, race/ethnicity, sex, stage of disease, functional status)
Addeo, 2010 <sup>194</sup>	Italy Multicenter 2003 – 2005	A: MMC, 40 mg (in 50 mL normal saline). Total 5 instillations: First within 2 days after TURBT, then 4 weekly treatments. (n=55)  B: Gemcitabine, 2,000 mg (in 50 mL normal saline). "6-week induction course of infusion", dosing not otherwise specified. (n=54)  A and B: Maintenance therapy of 10 monthly treatments for initial responders who remained free of recurrence.	Duration: 36 months (median) for each group  Method: Not reported	Age (mean), years: 67.9 vs. 64.9 Age (median), years: 70 vs. 66.5 Male: 85.5% vs. 85.2% Race/ethnicity: Not reported Smoking status: Not reported Recurrent bladder cancer: 100% vs. 100% (recurrent only) Stage: Ta: 63.6% vs. 68.5%; T1: 36.4% vs. 31.5% Grade: G1: 25.5% vs. 20.4%; G2: 49.1% vs. 51.9%; G3: 25.5% vs. 27.8% Functional Status: Not reported
Akaza, 1987 <sup>112</sup> Study One (followup of Nijima, 1983 <sup>116</sup> )	Japan Multicenter 1980 – 1985	A: Doxorubicin, 30 mg (in 30 mL saline). Total 8 instillations. (n=149)  B: Doxorubicin, 20 mg (in 40 mL saline). Total 8 instillations. (n=148)  C: MMC: 20 mg (in 40 mL saline). Total 8 instillations. (n=139)  D: No adjuvant treatment. TURBT alone. (n=139)  For A, B, and C: First instillation within 1 week of TURBT. Twice weekly X 4 weeks	Duration: 5 years (maximum), overall.  Method: cystoscopy and urinary cytology.	Age (average), years: 62.3 vs. 62.9 vs. 62.9 vs. 62.9 Male: 82.6% vs. 75.7% vs. 74.8% vs. 74.1% Race/ethnicity: Not reported Smoking status: Not reported Recurrent bladder cancer: 29.5% vs. 31.1% vs. 33.8% vs. 35.3% Stage: Not reported Grade: Not reported Functional Status: Not reported Size: <1 cm: 40.3% vs. 37.2% vs. 43.9% vs. 46.0%; 1-3 cm: 43.0% vs. 52.7% vs. 38.8% vs. 48.2%; 3-5 cm: 14.8% vs. 74.3% vs. 12.2% vs. 5.0% Number of tumors: 1: 64.4% vs. 63.5% vs. 48.2% vs. 60.4%; 2-4: 26.2% vs. 25.7% vs. 39.6% vs. 30.2%; 5+: 80.5% vs. 10.8% vs. 11.5% vs. 9.4%

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
BCG Trials	Badalament, 1987 <sup>200</sup> USA Single center 1981-1984	Recurrent Ta, T1, or Tis bladder cancer without immediate indication for cystectomy who underwent BCG induction therapy	A: BCG Pasteur strain 120 mg (in 50 mL sterile saline) weekly for 6 weeks starting at 2-3 weeks after TURBT, then monthly  B: BCG Pasteur strain 120 mg (in 50 mL sterile saline) weekly for 6 weeks	93/unclear	Duration, median 22 months (range 3 to 44 months)  Method: Cystoscopy 3-5 weeks after induction, then every 3 months, with cytology
	Fellows, 1994 <sup>201</sup> UK Multicenter 1988-1991	Histologically proven recurrent multiple pTa/pT1 bladder tumors difficult to control endoscopically	A: BCG Evans strain (1-5 x 10 <sup>9</sup> CFU)  B: BCG Pasteur strain (1-3 x 10 <sup>9</sup> CFU)  6 weekly instillations	99/97	Duration: 3 months  Method: Cystoscopy 3 months after start of BCG
	Gruenwald, 1997 <sup>215</sup> Israel Single center 1992-1994	Multifocal (≥3) tumors of any stage or grade, ≥3 recurrences within 12 months (regardless of stage), concomitant Tis, stage T1, or grade G3	A: Pasteur strain BCG 120 mg/50 mL saline (begun within 1 month after TURBT, once weekly for 6 weeks) B: Pasteur strain BCG 120 mg/50 mL saline (begun within 1 month after TURBT, once weekly for 12 weeks)	89/89	Duration, median: 29 months  Method: Cystoscopy and cytology every 3 months during year 1, every 6 months during year 2
	Hinotsu, 2011 <sup>176</sup> Japan Multicenter 2004-2006	Recurrent or multiple tumors with confirmed Ta or T1 transitional cell carcinoma; must have 1 of the following: (a) at least 3 tumors (b) recurrence is at least the third such event or with recurrence diagnosed within 12 months from previous TURBT for NMIBC	Within 1 month of TURBT: A. BCG 81 mg (Connaught strain) in 40 mL saline weekly for 6 weeks then once weekly for 3 weeks at 3, 6, 12, and 18 months from start of induction therapy B. BCG 81 mg (Connaught strain) in 40 mL saline weekly for 6 weeks C. Epirubicin 40 mg in 40 mL saline twice at 1-week interval and then 7 times at 2-week intervals	116/110	Duration, median: 2 years  Method: Cystoscopy and cytology every 3 months for 3 years then every 6 months
	Inamoto, 2013 <sup>204</sup> Japan Single center 2008-2009	Histologically proven, single or multiple, primary or recurrent, stage Ta, T1, grades 1-3 urothelial carcinoma of the bladder, or carcinoma in situ.	A: Tokyo 172 strain BCG 40mg in 40 mL of saline  B: Connaught strain BCG 81 mg in 40 mL of saline  Given for six consecutive weeks starting 14 days after TURBT	38/38	Duration: Median followup: 16.4 months vs. 16.5 months  Method: Cystoscopy and urine cytology every 3 months

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
	Irie, 2003 <sup>218</sup> Japan Single center 1996-2001	Superficial papillary bladder cancer, no prior BCG or chemotherapeutic agents, stage Ta or T1	A. BCG (Tokyo 172 strain) 40 mg/40 mL saline, 6 instillations weekly starting 7-50 days after TURBT B. BCG (Tokyo 172 strain) 80 mg/40 mL saline, 6 instillations weekly starting 7-50 days after TURBT	Not Reported/ 80	Duration, mean: 27.5 months in 40 mg group and 20 months in 80 mg group  Method: Cystoscopy and cytology every 3 months for 2 years, then every 6 months
	Koga, 2010 <sup>205</sup> Japan Multicenter 2002-2005	Histologically-confirmed Ta, T1 transitional cell carcinoma or CIS of bladder, responded to induction therapy	BCG 80 mg (Tokyo strain) within 4 weeks of biopsy or TURBT and repeated weekly for 8 weeks; patients with complete response were randomized to:  A. BCG 80 mg (Tokyo strain) within 3 months of randomization followed by instillations at 3, 6, and 9 months  B. No BCG	53/51	Duration: Median followup: 27 vs. 29 months  Method: Cytology and cystoscopy 2 months after randomization and then every 3 months for 3 years and thereafter every 6 months
	Lamm, 2000 <sup>206</sup> USA Multicenter 1986-1989  Lerner, 2007 <sup>207</sup>	Histologically confirmed transitional cell carcinoma of the bladder within 6 months before enrollment; papillary tumors Ta or T1; 2 tumors (primary and recurrent or 2 recurrences) within 1 year, 3 or more within the most recent 6 months and/or CIS, responded to induction therapy with BCG	At least 1 week following TURBT patients received BCG 81 mg (Connaught strain) in 50.5 mL saline and simultaneous percutaneous BCG 0.5 cc (10 <sup>7</sup> CFU) to inner thigh weekly for 6 weeks, responders randomized to:  A. BCG intravesically and percutaneously 3 successive weekly treatments at 3 months, 6 months and every 6 months to 3 years  B. No BCG	550/384	Duration: Median followup: 120 months  Method: Cytology and cystoscopy every 3 months for 2 years then every 6 months for 2 years then yearly
	Martinez-Pineiro, 2002 <sup>222</sup> Spain Multicenter 1991-1992	Primary or recurrent TaG2/3 or T1G1-3 bladder cancer with or without CIS; primary Tis; recurrent TaG1 cancers	A: BCG Connaught strain 81 mg, 12 instillations (starting 7 to 14 days after TURBT, once weekly for 6 weeks, then once every 2 weeks for 12 weeks) B: BCG Connaught strain 27 mg, 12 instillation (starting 7 to 14 days after TURBT, once weekly for 6 weeks, then once every 2 weeks for 12 weeks)	500/499	Duration, median: 69 months  Method: Not reported

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
	Martinez-Pineiro, 2005 <sup>223</sup> Spain Multicenter 1995-1999	T1G3 and Tis bladder cancer	A: BCG Connaught strain 81 mg, 12 instillations (starting 7 to 14 days after TURBT, once weekly for 6 weeks, then once every 2 weeks for 12 weeks) B: BCG Connaught strain 27 mg, 12 instillation (starting 7 to 14 days after TURBT, once weekly for 6 weeks, then once every 2 weeks for 12 weeks)	155/ 155	Duration, median: 61 months  Method: Not reported
	Morales, 1992 <sup>226</sup> Canada Single center 1979-1988	Tis or T1 transitional cell carcinoma of the bladder with residual neoplasm; in patients with recurrences must have had a least 2 histologically documented but completely ablated tumors on 2 separate cystoscopic studies in the last 12 months	A: Armand Frappier BCG 60 mg weekly for 6 weeks B: Armand Frappier BCG 120 mg weekly for 6 weeks	97/97	Duration, mean: 21 months  Method: Cystoscopy at 4, 12, and 24 weeks, then at 6 to 12 months
	Mukherjee, 1992 <sup>208</sup> UK Single center 1984- unclear end date	Multiple recurrent superficial bladder tumors that were increasingly difficult to keep under endoscopic control	A: BCG Glaxo strain (1.2 x 10 <sup>9</sup> CFU) B: BCG Pasteur strain (1.2 x 10 <sup>9</sup> CFU)  6 weekly instillations, followed by either monthly instillations if there was a complete response or 6-weeks if there was a partial or no response.	21/21	Duration: mean 60 months  Method: Cystoscopy 3 months after final instillation, and then according to clinical criteria

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
	Oddens, 2013 <sup>228</sup> Europe Multicenter 1997-2005	Solitary T1G3 or multiple Ta-T1, G1-3 urothelial carcinoma of the bladder	A: BCG (OncoTICE strain) 5 x 10 <sup>8</sup> CFU at 1/3 dose, 15 instillations (started within 14 days after TURBT, one weekly for 6 weeks, then 3 weekly instillations at months 3, 6, and 12) B: BCG full dose, 15 instillations (started within 14 days after TURBT, one weekly for 6 weeks, then 3 weekly instillations at months 3, 6, and 12) C: BCG at 1/3 dose, 27 instillations (started within 14 days after TURBT, one weekly for 6 weeks, then 3 weekly instillations at months 3, 6, 12, 18, 24, 30, and 36) D: BCG full dose, 27 instillations (started within 14 days after TURBT, one weekly for 6 weeks, then 3 weekly instillations at months 3, 6, 12, 18, 24, 30, and 36)	1805/ 1355	Duration, median: 7.1 years  Method: Cystoscopy and cytology every 3 months for 3 years, then every 6 months
	Ojea, 2007 <sup>151</sup> Spain Multicenter 1995-1998	Intermediate risk with stages TaG2 and T1G1-2 superficial bladder tumors without carcinoma in situ	14-21 days after transurethral resection with histological confirmation of bladder cancer, patients received 6 weekly instillations then another 6 instillations one every 2 weeks; if a recurrence was diagnosed a further TURBT was performed and the treatment continued  A. BCG 27 mg (Connaught strain) B. BCG 13.5 mg (Connaught strain) C. MMC: 30 mg	430/397	Duration, median: 57 months vs. 61 months vs. 53 months  Method: Cystoscopy every 3 months during first year and then every 4 months for the next 4 years
	Pagano, 1995 <sup>230</sup> Bassi, 1992 <sup>262</sup> (Abstract of interim results) Italy Single center 1990	Multiple papillary tumors (Ta-T1) and CIS	6-week course of intravesical therapy:  A. Pasteur strain BCG 75 mg B. Pasteur strain BCG 150 mg	Not Reported/ 138	Duration: Not reported  Method: Not reported

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
	Palou, 2001 <sup>209</sup> Spain, England Multicenter 1989-1995	Primary or relapsing stage Ta or T1 grade 3 superficial bladder tumors with or without associated CIS or isolated CIS or associated with grade 2 superficial bladder tumors, responded to induction therapy with BCG	Initial treatment with 6 weekly instillations of BCG 81 mg (Connaught strain); if relapse then 6 additional weekly instillations; if disease free then randomized to:  A. BCG 81 mg (Connaught) 6 weekly instillations every 6 months for 2 years  B. No further treatment	131/126	Duration: Median followup 78 months  Method: Alternating cytology and cystoscopy every 3 months for 2 years and then cytology and cystoscopy every 6 months
	Rentsch, 2014 <sup>210</sup> Switzerland Single center 1998-2010	High risk NMIBC (any high-grade tumor, any low-grade tumor with more than two recurrences within 2 years, or carcinoma in situ)	A: BCG Connaught (6.6-19.2 x 10 <sup>8</sup> CFU)  B: BCG Tice (2-8 x 10 <sup>8</sup> CFU)  6 weekly intravesical instillations	142/131	Duration: Median 47.6 vs. 51.4 months  Method: Cystoscopy and cytology at 3-month intervals for the first 3 years, then at 6-month intervals for the following 2 years. Urography or CT scan at 1 and 3 years after BCG.
	Sengiku, 2013 <sup>233</sup> Japan Single center 2004-2012	Stage Ta/T1 or Tis, multiple tumors and recurrence-free period of 3 months or less	At least 2 weeks after removing as much of visible lesion as possible by TURBT, patients received weekly up to 8 times:  A. BCG 80 mg (Tokyo strain) in 40 mL saline B. BCG 81 mg (Connaught strain) in 40 mL saline	178/129	Method: Cystoscopy and urine cytology every 3 months for first 2 years and every 3-6 months thereafter

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

Trial Type	Author, Year Setting Study Years	Inclusion Criteria	Interventions	Number Randomized/ Analyzed	Duration and Method of Followup
	Witjes, 1993 <sup>148</sup> Witjes, 1996 <sup>156</sup> Vegt, 1995 <sup>211</sup> The Netherlands Multicenter 1987-1990	Histologically proven papillary pTa-pT1 transitional cell carcinoma of the bladder with or without CIS	A. MMC 30 mg in 50 mL saline once a week for 4 weeks and thereafter once a month for 5 months. If a superficial recurrence or persistent CIS after 6 months, 3 additional monthly instillations given B. BCG-Tice C. BCG RIVM  BCG 5X108 bacilli in 50 mL saline, administered once a week for 6 weeks. At the time of first superficial recurrence or persistent CIS at 3 or 6 months, a second 6 week course with BCG instillations was given after complete TURBT or biopsy.	469/437	Duration, median: 32 months  Method: Cystoscopy every 3 months for 2 years, every 4 months in years 3 and 4 and every 6 months thereafter
MMC Trials	Au, 2001 <sup>197</sup> USA, Europe, and Canada Multicenter 1992-2000	Transitional cell carcinoma of bladder at high risk for recurrence based on 1) two or more episodes of Ta, Tis, or T1 cancers, 2) multifocal (≥3 papillary tumors or Tis involving ≥25% of bladder surface and/or in two or more biopsy sites), 3) tumors >5 cm, G3, or DNA aneuploidy	A: MMC 40 mg/20 mL sterile water, 6 instillations (once weekly for 6 weeks), optimized by instruction to refrain from fluids for 8 hour prior to and during instillations, oral doses of 1.3 g sodium bicarbonate the night before, Foley to empty bladder prior to instillation for post void residual <10 mL B: MMC 20 mg/20 mL sterile water, 6 instillations (once weekly for 6 weeks), without additional optimization measures	230/201	Duration: 5 years  Method: Cystoscopy and cytology every 3 months for 2 years, every 6 months for years 3-5, and once yearly thereafter
	Colombo, 2012 <sup>213</sup> Italy Single center 2010-2011	Recurrent, single, small (<1.5 cm) bladder cancers following TURBT of low-grade NMIBC	A: Mitomycin C (MMC), 40 mg (in 40 mL saline) three instillations per week for 2 weeks, prior to TURBT  B: Mitomycin C (MMC), 40 mg (in 40 mL saline) one instillation per week for 6 weeks, prior to TURBT	54/54	Duration, 9 to 11 days following end of instillations  Method: Cystoscopy with 14 days of completion of therapy

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
	Ersoy, 2013 <sup>198</sup> Turkey Single center 2006- 2010	Primary low-risk NMIBC. Stage Ta, Grade G1. Solitary tumor; Size <3 cm.	A: MMC, 40 mg (in 40 mL sterile saline) intravesical; infusion within 6 hours of TURBT; MMC retained in bladder for 2 hours. B: Urinary alkalinization prior to MMC instillation: Sodium bicarbonate, 1.3 g, orally X 3 doses (night before TURBT, morning of TURBT, 30 minutes prior to MMC). MMC, 40 mg (in 40 mL sterile saline) intravesical; infusion within 6 hours of TURBT; MMC retained in bladder for 2 hours. C: No drugs given in the first 6 hours after TURBT.	53/49	Duration, median: A vs. B vs. C: 51 vs. 50 vs. 54 months, p=0.815  Method: Cystoscopy: month 3, month 12, then annually for 5 years.
	Friedrich, 2007 <sup>154</sup> Germany Multicenter 1995-2002	Patients with primary transitional cell carcinoma of the bladder or patients with tumor recurrence after TURBT without prior adjuvant; histopathologic evaluation of their completely resected tumor revealed an intermediate risk pTaG1 tumor (size >3 cm, recurrent or multifocal tumor) or pTaG2 up to pT1 tumor (G1-3). Patients with T1G3 tumor were eligible in case of a unifocal small tumor (≤2.5 cm).	A. MMC 20 mg, 6 weekly instillations B. BCG RIVM 2 x 10 <sup>8</sup> CFU, 6 weekly instillations C. MMC 20 mg, 6 weekly instillations followed by monthly instillations of MMC 20 mg for 3 years	495/ 495	Duration, median: 2.9 years  Method: Cytology and cystoscopy every 3 months in the first 2 years and every 6 months thereafter
	Fukui, 1992 <sup>202</sup> Japan Single center 1986-1989	Ta, T1, or Tis transitional cell carcinoma of the bladder who had complete response to 5 weeks induction therapy with sequential MMC and adriamycin	A: MMC 20 mg (in 20 mL saline) on day 1 and adriamycin 40 mg (in 20 mL saline) on day 2 for 5 weeks, followed by maintenance therapy once monthly for 12 months  B: MMC 20 mg (in 20 mL saline) on day 1 and adriamycin 40 mg (in 20 mL saline) on day 2 for 5 weeks, No maintenance therapy	51/51	Duration: Unclear  Method: Cystoscopy and urine cytology every 3 months

Doxorubicin Trials	Akaza, 1987 <sup>112</sup> Japan Unclear if single or multicenter 1982-1985	Histologically proven superficial bladder cancer (primary only). Stages Ta or T1; Grade G1 or G2. Absence of tumor after TURBT.	A: Doxorubicin, 30 mg (in 30 mL saline). B: Doxorubicin, 20 mg (in 40 mL saline). C: MMC: 20 mg (in 40 mL saline). D: No adjuvant treatment. TURBT alone.  For A, B, and C: First instillation within 1 week of TURBT. Once weekly X 2 weeks, then once every 2 weeks X 14 week, then once monthly X 8 months, then once every 3 month X 1 year (Total: 21 doses over 2 years)	665/607	Duration: 3.5 years, maximum; Mean, median not reported  Method: Cystoscopy and urinary cytology studies at 12-week intervals throughout study period
	Flamm, 1990 <sup>214</sup> Austria Single center 1979-1981	Primary or recurrent transitional cell carcinoma of the bladder, otherwise not specified	A: Doxorubicin 50 mg/50 mL saline weekly for 6 weeks, then monthly for 2 years B: Doxorubicin 50 mg/50 mL saline weekly for 6 weeks	160/146	Duration: 5 years  Method: Cystoscopy every 3 months for 2 years, then every 6 months
	Matsumura, 1992 <sup>123</sup> Japan Multicenter 1987-1989	Ta, T1, or Tis transitional cell carcinoma of the bladder; primary with multiple lesions or recurrent with one or more lesions	A: Doxorubicin 20 mg/40 mL saline, 21 instillations (following TURBT, once weekly for 2 weeks, then every 2 weeks for 14 weeks, once monthly for 8 months, and once every three months for 1 year) B: Doxorubicin 20 mg/40 mL saline, 6 instillations (over 2 weeks prior to TURBT) C: No doxorubicin	443/284	Duration, median: 240 days  Method: Not reported
	Niiijima, 1983 <sup>116</sup> Japan Multicenter 1980 – 1985	Histologically proven superficial bladder cancer (primary or recurrent). Stages Ta or T1; Grade not specified. Absence of tumor after TURBT.	A: Doxorubicin, 30 mg (in 30 mL saline). B: Doxorubicin, 20 mg (in 40 mL saline). C: MMC: 20 mg (in 40 mL saline). D: No adjuvant treatment. TURBT alone.  For A, B, and C: First instillation within 1 week of TURBT. Twice weekly X 4 weeks (Total: 8 doses)	707/575	Duration: 5 years, maximum; Mean/Median not reported  Method: Cystoscopy and urinary cytology studies at 12-week intervals during the observation period.

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
	Rubben, 1988 <sup>231</sup> Germany Single center 1979-1981	Primary or recurrent NMIBC, any grade	A: Doxorubicin 50 mg/50 mL saline, 13 instillations (2 hours prior to TURBT, then twice weekly for 6 weeks) B: Doxorubicin 50 mg/50 mL saline, 28 instillations (2 hours prior to TURBT, then twice weekly for 6 weeks, twice monthly for 4.5 months, once monthly for 6 months) C: No intravesical therapy	965/834	Duration: Mean, median not reported  Method: Cystoscopy and cytology every 3 months for 2 years, then every 6 months
	Ueda, 1992 <sup>236</sup> Japan Multicenter 1984-1986	Ta and T1 transitional cell carcinoma of bladder	A: Doxorubicin 30 mg/30 mL saline, 19 instillations (immediately and 2 days after TURBT, then weekly for 2 weeks, every 2 weeks for 14 weeks, monthly for 8 months) B: Doxorubicin 30 mg/30 mL saline, 19 instillations (immediately and 2 days after TURBT, then weekly for 2 weeks, every 2 weeks for 14 weeks, monthly for 8 months) plus 5-fluorouracil 200 mg/day starting at 1 week C: Doxorubicin 30 mg/30 mL saline, 17 instillations (starting 7 days after TURBT weekly for 2 weeks, every 2 weeks for 14 weeks, monthly for 8 months)	275/187	Duration, mean: 31 months  Method: Cystoscopy at 4 weeks then every 3 months

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
Epirubicin Trials	Ali-El-Dein, 1997 <sup>119</sup> (J Urol) Egypt Single center 1991 – 1995	TCC of the bladder (primary or recurrent). Stages Ta or T1; Associated CIS or other dysplastic mucosal changes; Grade G1 - G3. Rapid recurrence within 6 months of initial resection; Multicentricity; Positive posterior urethral biopsy and/or positive postoperative urinary cytology (only 2 patients with positive posterior urethral biopsy, who underwent resection of multiple tumors to provide bladder neck incompetence and sufficient contact of drug with prostatic urethra).	A: Epirubicin, 50 mg (in 50 mL normal saline). B: Epirubicin, 80 mg (in 50 mL normal saline). C: Doxorubicin, 50 mg (in 50 mL normal saline). D: No adjuvant treatment. TURBT alone.  For Groups A - C: First instillation 7 to 14 days after TURBT. Retained intravesically for 2 hours; Instillations once a week X 8 weeks, then once monthly to complete 1 year of treatment.	253/ 253	Duration, mean: 30.1 months  Method: Cystourethroscopy, urine cytology, and flow cytometry every 3 months during first 2 years, and every 6 months thereafter.
	Ali-El-Dein, 1997 <sup>126</sup> (British J Urol) Egypt Single center 1992 – 1996	TCC of the bladder (primary or recurrent). G2 or G3, multiple recurrent, pT1, aneuploidy, or $\geq 3$ cm; pTa if multiple, large ( $\geq 3$ cm), recurrent and/or grade 2-3 tumors.	A: Epirubicin, 50 mg (in 50 mL normal saline); Single instillation immediately after TURBT. Retained intravesically for 2 hours. B: Epirubicin, 50 mg (in 50 mL normal saline); Initial instillation 1 - 2 weeks after TURBT. Retained intravesically for 2 hours; Then, instillations once a week X 7, then once monthly X 10 to complete 1 year of treatment. C: No adjuvant treatment. TURBT alone.	179/168	Duration, mean: 32.2 months  Method: Cystourethroscopy, cytology, and DNA flow cytometry 8 weeks after resection, then every 3 months during first 2 years, and every 6 months thereafter during the next 2 years.

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
	Nomata, 2002 <sup>227</sup> Japan Multicenter 1995-1998	Ta or T1/G1 or G2 transitional cell carcinoma of the bladder, ECOG performance status 0 or 1, age 20 to 80 years, post TURBT with no evidence of residual cancer based on cytological evaluation of voided urine	A. Epirubicin 30 mg/30 mL saline 19 times over 1 year (once weekly for 4 weeks, then every 2 weeks for 4 months) B. Epirubicin 30 mg/30 mL saline 12 times over 5 months (once weekly for 4 weeks, then every 2 weeks for 4 months, then once per month for 7 months)	138/125	Duration, median: 18.1 months  Method: Cystoscopy every 3 months
	Okamura, 1998 <sup>229</sup> Japan Multicenter 1991-1993	Ta-T1 papillary bladder cancer resectable by TURBT, ECOG performance status 0 or 1, age <85 years; primary or recurrent bladder cancer if recurrence-free interval >1 year	A: Epirubicin 40 mg/40 mL saline 17 times (within 24 hours of TURBT, during first week, once weekly for 4 weeks, then once monthly for 11 months) B: Epirubicin 40 mg/40 mL saline 6 times (within 24 hours of TURBT, during first week, then once weekly for 4 weeks)	148/138	Duration, median: 29.6 months  Cystoscopy and cytology at 4 weeks, then every 3 months
	Saika, 2010 <sup>134</sup> Japan Multicenter 1995 – 2001	Transitional cell carcinoma of the bladder (primary or recurrent). Stages Ta or T1; Grade G1, G2, or G3. Age ≥20 years.	A. Epirubicin, 20 mg (in 40 mL physiological saline). Two intravesical infusions, one immediately after (<1 hour) TURBT and one in the early morning of the following day, retained in bladder for 1 hour. B. Epirubicin, 50 mg (in 100 mL physiological saline). Same procedure as A. C. No adjuvant therapy. TURBT only.	303/240	Duration, median: Overall: 44 months; A vs. B vs. C: 44 vs. 46 vs. 42  Method: Cystoscopy every 3 months for 2 years and every 6 months thereafter.
	Serretta, 2010 <sup>234</sup> Italy Multicenter 2002-2003	Multiple and recurrent Ta tumors; recurrent, single or multiple T1 tumors	A: Epirubicin 80 mg/50 mL saline, 16 instillations (within 6 hours of TURBT, then once weekly for 5 weeks, once weekly for 10 months) B: Epirubicin 80 mg/50 mL saline, 6 instillations (within 6 hours of TURBT, then once weekly for 5 weeks)	482/395	Duration, median: 48 months  Method: Cystoscopy and cytology every 3 months for 2 years, then 6 months from years 3 to 5

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
	Turkeri, 2010 <sup>235</sup> Turkey Multicenter 2002-2004	Primary bladder tumor, ≤3 lesions, Ta (G2 or G3) or T1 (G1 or G2)	A: Epirubicin 100 mg within 6 hours after TURBT B: Epirubicin 100 mg within 6 hours and 12-hours after TURBT	299/143	Duration, mean: 16.9 months  Method: Cystoscopy every 3 months for 1 year, then every 6 months during years 2 and 3, then once yearly
Gemcitabine Trials	Gardmark, 2007 <sup>157</sup> Japan Single center 1986-1989	Recurrent multiple Ta G1/2 bladder cancer, with all lesions except one marker lesion resected	A: Gemcitabine 2000 mg (in 100 mL saline) once weekly for 6 weeks  B: Gemcitabine 2000 mg (in 100 mL saline) twice weekly for 3 weeks  C: Gemcitabine 2000 mg (in 100 mL saline) single instillation	32/30	Duration: 9 weeks after initial instillation  Method: Cystoscopy
Thiotepa Trials	Koontz, 1981 <sup>140</sup> (prophylaxis) USA Multicenter 1974-1977	Multifocal NMIBC or bladder cancer on ≥3 occasions in last 18 months; clinical assessment that prophylaxis warranted (2 tumors within 6 months); or complete response to thiotepa	A: Thiotepa 30 mg/30 mL distilled water (once every 4 weeks for maximum 2 years) B: Thiotepa 60 mg/60 mL distilled water (once every 4 weeks for maximum 2 years) C: No thiotepa	95/93 (30 responders from Koontz 1981 thiotepa treatment trial enrolled)	Duration, median: 15 months  Method: Cystoscopy every 3 months
	Koontz, 1981 <sup>140</sup> (treatment) USA Multicenter 1974-1977	Incompletely resected NMIBC (single or multiple) or Tis or carcinoma on random biopsy	A: Thiotepa 30 mg/30 mL distilled water (once weekly for 4 weeks, repeated after 4 weeks) B: Thiotepa 60 mg/60 mL distilled water (once weekly for 4 weeks, repeated after 4 weeks)	101/95	Duration: 4 weeks after 2 4-week treatment courses  Method: Cystoscopy at 4 weeks after fourth instillation and 4 weeks after eight instillation

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

<b>Trial Type</b>	<b>Author, Year Setting Study Years</b>	<b>Inclusion Criteria</b>	<b>Interventions</b>	<b>Number Randomized/ Analyzed</b>	<b>Duration and Method of Followup</b>
Interferon alpha-2b Trials	Giannakopoulos, 1998 <sup>136</sup> Greece Unclear if single or multicenter Study years not reported	Superficial transitional cell carcinoma (TCC) of the bladder (primary or recurrent). Stages Ta or T1; Grade G2.	A: No adjuvant treatment. TURBT alone. B: Interferon- $\alpha$ -2b (interferon- $\alpha$ -2b), 40 MU (in 50 mL normal saline). C: Interferon- $\alpha$ -2b (interferon- $\alpha$ -2b), 60 MU (in 50 mL normal saline). D: Interferon- $\alpha$ -2b (interferon- $\alpha$ -2b), 80 MU (in 50 mL normal saline).  For Groups B - D: First instillation after histological verification of stage and grade; 48 - 72 hours after TURBT. Retained intravesically for 1 hour; patient position changed every 15 minutes. Instillations once a week X 2 months, then once every 15 days X 4 months, then once monthly X 6 months.	89/89	Duration: 36 months  Method: Cystoscopy and urine cytology, every 3 months for 18 months, and every 6 months thereafter.
	Glashan, 1990 <sup>203</sup> USA, Europe, Australia, Canada Multicenter 1985-1988	Carcinoma in situ of the bladder and positive post-biopsy cytology	A: Interferon $\alpha$ -2b 100 million units (in 30 mL sterile water) B: Interferon $\alpha$ -2b 10 million units (in 30 mL sterile water)  First instillation within 1 month of positive cytology, administered once weekly for 12 weeks, then monthly through one year	85/80	Duration: 36 months  Method: Cystoscopy and cytology every 3 months
	Hoeltl, 1991 <sup>217</sup> Austria Single center Study years not reported	Primary G1 or G2 papillary transitional cell carcinoma of bladder stages Ta, T1, or TIS or recurrent G1/Ta or T1 bladder cancer; Karnofsky performance status $\geq 50\%$	A: Interferon alfa-2b 100 x 10 <sup>6</sup> IU (100 MU)/30 mL sterile water (once weekly for 10 weeks, then once monthly for 1 year total of therapy) B: Interferon alfa-2b 10 x 10 <sup>6</sup> IU (10 MU)/30 mL sterile water (starting within 36 hours of TURBT, once weekly for 10 weeks, then once monthly for 1 year total of therapy) C: Ethoglucid 1.13 g/100 mL sterile water (once weekly for 10 weeks, then once monthly for 1 year total of therapy)	44/34	Duration, mean: 36.5 months  Method: Cystoscopy and urine cytology every 3 months for 1 year, then every 6 months

**Table 17. Study characteristics for trials comparing doses, duration, and timing of administration (continued)**

Trial Type	Author, Year Setting Study Years	Inclusion Criteria	Interventions	Number Randomized/ Analyzed	Duration and Method of Followup
	Malmström, 2002 <sup>221</sup> Europe Multicenter Study years: not reported	Histologically confirmed TCC of the bladder (primary or recurrent). Multiple tumors only. Stages Ta or T1; Grade G1 or G2. Karnofsky performance status >70%; No other malignancy within 5 years of the study, except nonmelanoma skin cancer; Age ≥18 years; Not pregnant and on appropriate birth control.	A: Interferon-α, 30 MU (in 30 mL sterile water). Retained in bladder X 2 hours; patient moved from side to side every 30 minutes. First instillation 1 to 2 weeks after TURBT or biopsy, then weekly X 12 weeks. B: Interferon-α, 50 MU (in 30 mL sterile water). Same procedure as A. C: Interferon-α, 80 MU (in 30 mL sterile water). Same procedure as A. D: MMC, 40 mg (in 40 mL sterile water). Retained in bladder X 2 hours; patient moved from side to side every 30 min. First instillation 1 to 2 weeks after TURBT or biopsy, then weekly X 8 weeks.	115/110	Method: followup at 9 weeks and 13 weeks for all treatment groups and at 9 weeks only for control group. Cystoscopy at week 9 for both groups.
Multiple Drugs	Bouffieux, 1995 <sup>212</sup> Europe Multicenter 1983-1986	Completely resectable, Ta or T1 (0 or A), papillary transitional cell carcinoma of the bladder (single or multiple, primary or recurrent), previous intravesical treatment with cytotoxic drugs other than MMC allowed if >3 months prior	Initial randomization: A. MMC 30 mg/50 mL saline or doxorubicin 50 mg, 9 instillations starting on day of TURBT (once weekly for 4 weeks, then once monthly for 5 months) B. MMC 30 mg/50 mL saline or doxorubicin 50 mg, 9 instillations, starting between days 7 and 15 after TURBT (once weekly for 4 weeks, then once monthly for 5 months)  Second randomization at 6 months: A: Continued instillations once a month for 6 months, total 15 B: No maintenance	965/834	Duration, average: 2.75 to 6.5 years (varied by outcome)  Method: Cystoscopy every 3 months during year 1, every 4 months during year 2, every 6 months thereafter

BCG = bacillus Calmette-Guérin; BCG RIVM = RIVM strain of bacillus Calmette- Guérin; BCG-Tice = bacillus Calmette-Guérin Tice strain; CIS = carcinoma in situ; CFU = Colony Forming Unit; ECOG = Eastern Cooperative Oncology Group; G1 = Grade 1; G2 = Grade 2; G3 = Grade 3; MMC = Mitomycin C; MU = million units; NMIBC = non-muscle-invasive bladder cancer; pT1 = Tumor stage 1 determined by pathology; pTa = Tumor stage a determined by pathology; T1 = Tumor stage 1; Ta = Tumor stage a; TCC = transitional cell carcinoma; Tis = carcinoma in situ; TURBT = transurethral resection of the bladder tumor

First instillation 1 to 2 weeks after TURBT or biopsy, then weekly X 8 weeks.</p>	<p>A vs. B vs. C</p> <p>Complete response (macroscopic disappearance of marker lesion): 19% (5/27) vs. 30% (8/27) vs. 26% (7/27) at 9 weeks; 19% (5/27) vs. 33% (9/27) vs. 41% (11/27) at 13 weeks (<math>p&gt;0.05</math> for all comparisons)</p>			<p>A vs. B vs. C vs. D</p> <p>Adverse events reported: 37% (10/27) vs. 37% (10/27) vs. 48% (13/27) vs. 55% (16/29)</p> <p>Adverse events with frequency <math>\geq 10\%</math>, reported by treatment group:</p> <p>A: None</p> <p>B: Fever (11%); Pain (11%)</p> <p>C: Fever (11%); Pain (15%); Micturition frequency (11%)</p> <p>D: Pain (10%); Dysuria (10%); Hematuria (14%); Micturition disorder (14%); Micturition frequency (28%); UTI (10%)</p>

**Table 18. Results summary for trials comparing dosages, duration, and timing of administration (continued)**

Intervention	Author, Year Setting Study Years	Interventions	Progression	Recurrence	Mortality	Adverse Events
Multiple Drugs	Bouffieux, 1995 <sup>212</sup> Europe Multicenter 1983-1986	Initial randomization: A. MMC 30 mg/50 mL saline or doxorubicin 50 mg, 9 instillations starting on day of TURBT (once weekly for 4 weeks, then once monthly for 5 months) B. MMC 30 mg/50 mL saline or doxorubicin 50 mg, 9 instillations, starting between days 7 and 15 after TURBT (once weekly for 4 weeks, then once monthly for 5 months)  Second randomization at 6 months: A: Continued instillations once a month for 6 months, total 15 B: No maintenance	Early vs. delayed treatment Progression to invasive bladder cancer: 11% (40/374) vs. 10% (38/378) after 6.5 years Distant metastasis: 6% (24/412) vs. 6% (17/412) Second primary: 7% (28/412) vs. 6% (25/412) Maintenance vs. no maintenance Progression to invasive bladder cancer: 9% (26/303) vs. 8% (25/314) Distant metastasis: 4% (12/304) vs. 4% (13/314) Second primary: 5% (15/304) vs. 7% (21/314) (p=0.41)	Early vs. delayed treatment Time to first recurrence: 43% (161/374) vs. 49% (187/378) after 2.75 years (p=0.18, log-rank test) Recurrence rate: 0.27 vs. 0.33 (p=0.08) Maintenance vs. no maintenance Time to first recurrence: 43% (130/303) vs. 50% (156/314) after 3 years (p=0.20, log-rank test) Recurrence rate: 0.23 vs. 0.28 (p=0.20)	Early vs. delayed treatment Mortality: 19% (78/412) vs. 21% (86/412) (p=0.60)  Maintenance vs. no maintenance Mortality: 17% (53/304) vs. 20% (63/314)	Early vs. delayed Chemical cystitis requiring delay or discontinuation of therapy: 3% vs. 0% with MMC, 2.2% vs. 0.5% with doxorubicin  Systemic toxicity requiring discontinuation of instillations: 1.8% with MMC, 0.8% with doxorubicin

AE = adverse event; AOR = adjusted odds ratio; BCG = bacillus Calmette-Guérin; BCG RIVM = RIVM strain of bacillus Calmette-Guérin; BCG-Tice = bacillus Calmette-Guérin Tice strain; CFU = colony forming unit; CI = confidence interval; CIS = carcinoma in situ; G2 = Grade 2; G3 = Grade 3; HR = hazard ratio; IU = international unit; MMC = Mitomycin C; MU = million units; NS = not significant; OR = odds ratio; RR = risk ratio; T1 = Tumor stage 1; T2 = tumor stage 2; Ta = Tumor stage a; Tis = carcinoma in situ; TURBT = transurethral resection of the bladder tumor; UTI = urinary tract infection; WBC = white blood cell count

# Discussion

## Key Findings and Strength of Evidence

The key findings of this review are summarized in the summary of evidence table (Table 21) and the factors used to determine the overall strength of evidence grades are summarized in Appendix G.

Urinary biomarkers were associated with sensitivity for bladder cancer that ranged from 0.57 to 0.82 and specificity that ranged from 0.74 to 0.88, for positive likelihood ratios that ranged from 2.52 to 5.53 and negative likelihood ratios that ranged from 0.21 to 0.48. Findings were robust in sensitivity and stratified analyses. Evidence was strongest for quantitative NMP22, qualitative bladder tumor antigen (BTA), fluorescence in situ hybridization (FISH), and ImmunoCyt (strength of evidence [SOE]: moderate), and relatively sparse for other biomarkers (SOE: low). Across urinary biomarkers, sensitivity was greater for higher stage and higher grade tumors (SOE: high). For qualitative BTA, FISH, and ImmunoCyt sensitivity was somewhat higher for evaluation of patients with signs or symptoms of bladder cancer than for surveillance of patients previously treated for bladder cancer, but for quantitative nuclear matrix protein 22 (NMP22) there was no clear difference in diagnostic accuracy based on reason for obtaining the biomarker. Studies that directly compared the accuracy of quantitative NMP22 and qualitative BTA found no differences in diagnostic accuracy (SOE: moderate). ImmunoCyt was associated with higher sensitivity than FISH (0.71, 95% CI 0.54 to 0.84 vs. 0.61, 95% CI 0.43 to 0.76, for a difference of 0.11, 95% CI 0.001 to 0.21) but lower specificity (0.71, 95% CI 0.62 to 0.79 vs. 0.79, 95% CI 0.71 to 0.85, for a difference of -0.08, 95% CI -0.15 to -0.001), based on three studies (SOE: low). There were too few head-to-head comparisons of other urinary biomarkers to reach firm conclusions regarding comparative accuracy. Sensitivity was increased when urinary biomarkers were used in conjunction with urine cytology than when the biomarker was used alone (SOE: moderate). No study evaluated clinical outcomes associated with use of urinary biomarkers for diagnosis or surveillance of bladder cancer (SOE: insufficient). Urinary biomarkers miss 18 to 43 percent of patients with bladder cancer and are incorrectly positive in 12 to 26 percent of patients without bladder cancer, which could result in delayed diagnosis or unnecessary cystoscopies and other diagnostic procedures, but no study directly measured effects of inaccurate diagnosis on clinical outcomes (SOE: insufficient). Most trials found fluorescent cystoscopy associated with decreased risk of subsequent bladder recurrence versus white light cystoscopy, but there was no difference in risk of progression or mortality, though data for these outcomes was relatively sparse (SOE: low). In addition, evidence on effects on risk of recurrence were inconsistent, and the only trial<sup>259</sup> designed to minimize performance bias (by blinding the cystoscopist to instillation of photosensitizer versus placebo) found no difference in risk of bladder cancer recurrence.

Intravesical therapy was effective for reducing risk of bladder cancer recurrence versus no intravesical therapy (Tables 19, 20). Versus no intravesical therapy, bacillus Calmette Guérin (BCG) was associated with decreased risk of bladder cancer recurrence (RR 0.63, 95% CI 0.50 to 0.79) as well as progression (RR 0.50, 95% CI 0.32 to 0.77) (SOE: moderate). Mitomycin C (MMC), doxorubicin, and epirubicin were also associated with decreased risk of bladder cancer recurrence versus no intravesical therapy (RR 0.66 to 0.80) but effects on bladder cancer progression were not statistically significant (MMC and epirubicin) or showed no effect (doxorubicin). Although trials varied with respect to doses, instillation regimens, and patient populations evaluated, findings were generally robust in sensitivity and subgroup analyses,

including exclusion of single dose instillation trials. No intravesical agent, including BCG, was associated with decreased risk of all-cause or bladder cancer specific mortality versus no intravesical therapy. However, evidence on the effectiveness of “optimized” MMC regimens on mortality was limited. Evidence on gemcitabine, interferon alpha, and thiotepa was sparse, and we found no randomized trials of valrubicin, paclitaxel, or apaziquone.

Head-to-head trials of intravesical therapy using different drugs showed few clear differences. For BCG versus MMC, the most well-studied comparison, there was no difference on any outcome, including bladder cancer recurrence, progression, or mortality (SOE: moderate). However, BCG was associated with decreased risk of bladder cancer recurrence in the subgroup of trials that evaluated maintenance regimens (SOE: low). Other head-to-head comparisons were evaluated in fewer trials, and showed few differences, though limited evidence suggested that BCG might be associated with decreased risk of bladder cancer recurrence and progression versus epirubicin (SOE: low). Although doxorubicin was associated with increased risk of bladder cancer recurrence versus epirubicin (RR 1.56, 95% CI 1.08 to 2.22), this finding was based on only three trials (SOE: low).<sup>119,195,196</sup>

Evidence to determine the effects of tumor characteristics on estimates of effectiveness of intravesical therapies was limited, but indicated no differences in risk estimates based on factors such as tumor stage, grade, multiplicity, recurrence status, and size (SOE: low). However, even if relative estimates of effectiveness are similar, absolute effects will vary depending on the underlying incidence of recurrence, progression, mortality, or other outcomes. Therefore, patients with higher stage, higher grade, multiple, recurrent, or larger tumors would be expected to experience greater absolute benefits. Evidence to determine the effects of patient characteristics such as age, sex, race/ethnicity, performance status, or comorbidities on estimates of effectiveness of intravesical therapies was not available, and evidence on comparative effectiveness of therapies for patients with recurrence or progression following treatment with BCG was limited to two small trials comparing different intravesical therapies.<sup>184,194</sup>

Trials that compared effects of intravesical therapy using different doses or instillation regimens for the same agent were difficult to interpret due to variability in the patient populations, doses, instillation regimens, and other factors. For BCG, there were no clear difference between standard and lower doses of BCG in risk of bladder cancer recurrence, progression, or mortality, including in patients with higher-risk non-muscle-invasive bladder cancer (NMIBC), but there was some inconsistency between trials (SOE: low). Limited evidence suggested that BCG maintenance regimens (>6 weeks) are more effective than induction regimens (≤6 weeks) at reducing risk of bladder cancer recurrence in responders to induction therapy or in patients with higher risk tumors (SOE: low). Head-to-head trials suggest that BCG TICE may be less effective than other BCG strains at reducing risk of recurrence, with no clear difference between non-TICE strains (SOE: low). Trials on the effects of dose and duration of other intravesical agents on outcomes reported inconsistent results and were clinically heterogeneous, making it difficult to draw strong conclusions (SOE: insufficient to low). However, there was no evidence that prolonging therapy for more than one year is more effective than shorter regimens.

Evidence on harms associated with intravesical therapies was more limited than evidence on benefits. Trials of BCG versus no intravesical therapy found that local and systemic adverse events were relatively common (granulomatous cystitis or irritative symptoms in 27% to 84% of patients, macroscopic hematuria in 21% to 72%, and fever in 27% to 44%) (SOE: low). BCG was also associated with an increased risk of local adverse events and fever versus MMC (SOE:

low). Standard dose BCG was associated with increased risk of local and systemic adverse events versus lower dose BCG. Few trials reported harms of intravesical agents other than BCG versus no intravesical therapy, or against another intravesical agent.

The only randomized trial of radiation therapy found no effects on recurrence, progression, or survival in patients with T1G3 cancers when compared against no radiotherapy (for unifocal cancers and no CIS) or against intravesical therapy (for multifocal disease or CIS) (SOE: low).<sup>239</sup>

## Findings in Relationship to What Is Already Known

Our findings on diagnostic accuracy were generally consistent with prior systematic reviews that found urinary biomarkers insufficiently accurate to replace cystoscopy.<sup>263-265</sup> Estimates for sensitivity and specificity were generally similar in our review and prior reviews, even though we excluded case-control studies and included more recently published studies. In addition, prior reviews did not evaluate potential differences in diagnostic accuracy for testing performed for evaluation of signs and symptoms of bladder cancer versus for surveillance.

Prior systematic reviews<sup>266,267</sup> found fluorescent cystoscopy associated with decreased risk of recurrent bladder cancer versus white light cystoscopy, but were published prior to a recent trial that was the only one to blind the cystoscopist to instillation of the photosensitizer and found no effect.<sup>259</sup> Like our report, prior reviews found no effect of fluorescent cystoscopy on risk of progression or mortality. Although prior reviews also found that fluorescent cystoscopy detected more bladder cancers on initial cystoscopy, this was not an assessed outcome for our review.

Our findings regarding the comparative effectiveness and harms of intravesical therapies are generally consistent with prior reviews that found intravesical therapy associated decreased risk of bladder cancer recurrence versus no intravesical therapy,<sup>268,269</sup> and BCG associated with decreased risk of bladder cancer progression. Prior systematic reviews that focused on immediate single instillation therapy also found intravesical therapy to be more effective than no intravesical therapy in reducing risk of bladder cancer recurrence, a conclusion consistent with our finding of no clear difference in risk estimates based on the type of instillation regimen.<sup>270-272</sup> Like our review, prior systematic reviews found maintenance therapy with BCG associated with decreased risk of bladder cancer versus MMC, despite some differences in the trials that were included, definitions of maintenance therapy, and use of individual patient data in the prior review.<sup>273</sup> Our findings are also consistent with prior systematic reviews that found BCG associated with decreased risk of bladder cancer versus epirubicin,<sup>274</sup> that the evidence on intravesical gemcitabine is limited,<sup>275</sup> and that the optimal dose and duration of intravesical therapy cannot be determined based on the available evidence.<sup>276</sup>

## Applicability

Some issues could impact the applicability of our findings. Some studies of diagnostic accuracy did not report results separately for patients undergoing evaluation of signs and symptoms of bladder cancer and those undergoing surveillance, though there is some evidence that diagnostic accuracy may vary based on the indication for testing. Studies of intravesical therapy varied in the doses used, the timing, number, frequency, and duration or instillations, and other factors (e.g., the BCG strain), making it difficult to reach conclusions that are widely generalizable. In addition, trials varied with regard to tumor characteristics in the patient populations evaluated. Another factor that potentially impacts applicability is that most studies focused on effects of intravesical therapy on recurrence of bladder cancer. Fewer trials evaluated more potentially serious, distal outcomes such as progression or mortality. A number of studies

were conducted in Japan, where management of bladder cancer may differ from the U.S. Treatment studies tended to exclude patients with significant comorbidities or poor general performance status, which could limit applicability to these populations. Very little information was available to determine whether diagnostic accuracy or treatment effects vary according to patient factors such as age, sex, race/ethnicity, performance status, or comorbidities.

## Implications for Clinical and Policy Decisionmaking

Our review has implications for clinical and policy decisionmaking. As there are no studies evaluating effects of using urinary biomarkers for diagnosis or surveillance of bladder cancer on clinical outcomes, decisions regarding their use must necessarily be made on the basis of diagnostic test performance. Table 22 shows estimated probabilities for bladder cancer following use of urinary biomarkers, based on likelihood ratios calculated from pooled sensitivities and specificities. In populations with a pretest probability of 5 percent, the post-test probability increased to 16 to 24 percent following a positive result, and decreased to 1.8 to 2.5 percent following a negative result. In settings with a pretest probability of 20 percent, the post-test probability increased to 37 to 60 percent following a positive results, and decreased to 8.0 to 11 percent following a negative result. Whether urinary biomarkers are sufficiently accurate to rule out bladder cancer and thereby reduce the need for cystoscopy depends on the ability of clinicians to estimate the pretest probability of disease and the acceptable threshold for a missed or delayed diagnosis. Use of urinary biomarkers in combination with urinary cytology increases the sensitivity for bladder cancer, but still misses about 10 percent of cases.

Regarding fluorescent cystoscopy, studies have not shown an effect on progression or mortality and trials that found reduced risk of recurrence may have been affected by performance bias. These findings might inform decisions regarding widespread adoption of fluorescent cystoscopy. Cost may also impact decisions to use fluorescent cystoscopy and urinary biomarkers, but was outside the scope of this report.

Our findings also have implications for use of intravesical therapy. Although intravesical therapy was associated with decreased risk of bladder cancer recurrence, there were no clear effects on bladder cancer-specific or all-cause mortality, and intravesical therapies are associated with local and systemic adverse events. Our findings are consistent with guidelines that recommend BCG as first-line therapy,<sup>13,277</sup> as no intravesical agent was more effective than BCG at reducing risk of bladder cancer recurrence, BCG is the only intravesical agent associated with decreased risk of bladder cancer progression versus no intravesical therapy, and some evidence indicates that BCG is associated with decreased risk of bladder cancer recurrence versus other intravesical agents. However, BCG is also associated with a high risk of adverse events. Some evidence indicates that using lower than standard doses of BCG maintains effectiveness while reducing harms. Other evidence suggests that longer courses of therapy may be necessary for optimal effects, particularly in higher risk patients. Therefore, decisions to use intravesical therapy and regarding the intravesical agent, doses, and regimen selected should take into account the trade-offs between potential benefits, which are likely to be higher in patients at higher risk for disease progression, and harms.

## Limitations of the Review Process

Substantial statistical heterogeneity was present in most pooled analyses of diagnostic accuracy; this situation is common in meta-analyses of diagnostic accuracy.<sup>278-280</sup> As noted in the Cochrane Handbook for Systematic Reviews of Diagnostic Test Accuracy, “heterogeneity is to

be expected in meta-analyses of diagnostic test accuracy.”<sup>280</sup> To address the anticipated heterogeneity, we utilized random effects models to pool studies and stratified studies according to the reason that imaging was performed and the unit of analysis used. We also performed additional stratified and sensitivity analyses based on the reference standard used, study characteristics (such as country in which the study was conducted, factors related to risk of bias), patient characteristics, and technical factors related to the imaging tests under investigation. As noted previously, results were generally robust in sensitivity analyses, despite the heterogeneity. We also focused on evaluations of comparative test performance based on within-study comparisons of imaging modalities, which tended to be associated with less heterogeneity than pooled across-study estimates. A limitation of our analysis of within-group comparisons is that we had to treat the two compared groups as independent, because we had only aggregated data. Individual patient level data would be required to take into account the paired nature of the comparisons. Such correlations are generally positive and would be expected to result in more narrow confidence intervals. Although it is possible that this could have caused us to not detect statistically significant differences, the point estimates indicated very little difference between tests.

We did not construct summary receiver operating characteristic curves. Almost all studies of a specific urinary biomarker used the same definition for a positive test, including tests based on a quantitative threshold. Estimates of sensitivity and specificity at different thresholds are needed to construct informative ROC curves.<sup>25</sup>

Statistical heterogeneity was also present in some analyses of intravesical therapies and fluorescent cystoscopy. To address this, we used the Dersimonian-Laird random effects model to pool studies. The Dersimonian-Laird random effects model may result in confidence intervals that are too narrow when heterogeneity is present, particularly when the number of studies is small.<sup>29</sup> Therefore, we repeated analyses using the profile likelihood method, which resulted in similar findings. Regardless of the method used, meta-analyses based on small numbers of trials can underestimate statistical heterogeneity and must be interpreted with caution.<sup>29</sup> We also stratified trials according to factors such as risk of bias rating, dose, number of instillations, duration of followup, enrollment of patients with high-risk NMIBC, and other factors. Although statistical heterogeneity remained present in some analyses, with some unexplained outlier trials, results were generally robust.

We excluded non-English language articles and did not search for studies published only as abstracts. Because of small numbers of trials for meta-analyses involving intravesical therapies, we did not formally assess for publication bias using statistical or graphical methods for assessing sample size effects because of small numbers of studies, as research indicates that such methods can be seriously misleading in such situations.<sup>281,282</sup> For fluorescent cystoscopy, we found one relatively large trial that showed no effect on risk of recurrence versus white light cystoscopy, suggesting that publication bias could have impacted results.<sup>260</sup>

## Limitations of the Evidence Base

Several limitations of the evidence base limited our ability to reach strong conclusions with regard to several aspects of diagnosis and treatment of NMIBC. Other than quantitative NMP22, qualitative BTA, FISH, and ImmunoCyt, urinary biomarkers were assessed in small numbers of studies, resulting in less precise estimates. In addition, almost all studies on diagnostic accuracy of biomarkers had methodological shortcomings. In some studies of urinary biomarkers, patients with positive markers and normal cystoscopy were considered to be positive without biopsy,

which could result in verification bias and overestimation of diagnostic accuracy. In addition, most of the evidence on comparative accuracy was indirect, as relatively few studies directly compared the accuracy of two or more biomarkers against cystoscopy and histopathology.

For fluorescent cystoscopy, a limitation of the evidence base is that few trials reported effects on progression or mortality, and instead mostly focused on evaluating effects on recurrence. In addition, only one trial of fluorescent cystoscopy blinded the cystoscopist to whether the photosensitizer had been instilled, which may have a greater impact on assessments of recurrence due to performance bias related to knowledge of the type of initial cystoscopy performed.

A limitation of the evidence for all Key Questions addressed in our review is that very few trials were assessed as low risk of bias. Methodological shortcomings included failure to adequately describe randomization and allocation concealment methods and unblinded design. Findings would be stronger if more high-quality trials were available.

Other limitations include the lack of evidence on how use of urinary biomarkers impacts clinical outcomes (including harms), a single randomized trial on effects of radiation therapy for NMIBC, no trials on effects of using a risk-adapted approach, and no studies on effects of how using different surveillance intervals impacts outcomes. Few studies evaluated effects of patient characteristics such as age, sex, race/ethnicity, performance status, or comorbidities on diagnostic test performance or effectiveness of intravesical therapy.

## Research Gaps

We identified a number of important research gaps. Given the increased sensitivity of urinary biomarkers with cytology, studies on how this combination impacts use of cystoscopy and subsequent clinical outcomes might be helpful for determining its role in diagnosis or surveillance and in followup of patients with abnormal cystoscopy or atypical cytology. Randomized trials that adequately safeguard against performance bias associated with use of photosensitizers for fluorescent cystoscopy are needed to determine effects on recurrence, progression, and mortality. Additional head-to-head trials of intravesical therapies that use more standardized instillation regimens and doses, “optimized” instillation of MMC, report outcomes in subgroups stratified by patient and tumor characteristics, include long-term outcomes related to progression and mortality, and assess and report harms using more standardized methods would help clarify optimal treatment strategies. Studies to determine optimal strategies for management of patients with recurrence or progression after standard intravesical therapy are needed. Research is also needed on determine the effectiveness of risk-adapted approaches to guide selection of therapy, including use of nontraditional prognostic markers, effects of different surveillance intervals and protocols, and newer techniques such as electromotive administration of intravesical therapy.

**Table 21. Summary of the strength of evidence**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
Key Question 1. What is the diagnostic accuracy of various urinary biomarkers compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging) in 1) people with signs or symptoms warranting evaluation for possible bladder cancer or 2) people undergoing surveillance for previously treated bladder cancer?	Quantitative NMP22: sensitivity and specificity	Moderate	Sensitivity was 0.69 (95% CI, 0.62 to 0.75) and specificity 0.77 (95% CI, 0.70 to 0.83), based on 19 studies, for a positive likelihood ratio of 3.05 (95% CI, 2.28 to 4.10) and negative likelihood ratio of 0.40 (95% CI, 0.32 to 0.50).
	Qualitative NMP22: sensitivity and specificity	Low	Sensitivity was 0.58 (95% CI, 0.39 to 0.75) and specificity 0.88 (95% CI, 0.78 to 0.94), based on 4 studies, for a positive likelihood ratio of 4.89 (95% CI, 3.23 to 7.40) and negative likelihood ratio of 0.48 (95% CI, 0.33 to 0.71).
	Qualitative BTA: sensitivity and specificity	Moderate	Sensitivity was 0.64 (95% CI, 0.58 to 0.69; 22 studies) and specificity 0.77 (95% CI, 0.73 to 0.81; 21 studies), for a positive likelihood ratio of 2.80 (95% CI, 2.31 to 3.39) and negative likelihood ratio of 0.47 (95% CI, 0.30 to 0.55).
	Quantitative BTA: sensitivity and specificity	Low	Sensitivity was 0.65 (95% CI, 0.54 to 0.75) and specificity 0.74 (95% CI, 0.64 to 0.82), based on 4 studies, for a positive likelihood ratio of 2.52 (95% CI, 1.86 to 3.41) and negative likelihood ratio of 0.47 (95% CI, 0.37 to 0.61).
	FISH: sensitivity and specificity	Moderate	Sensitivity was 0.63 (95% CI, 0.50 to 0.75) and specificity 0.87 (95% CI, 0.79 to 0.93), based on 11 studies, for a positive likelihood ratio of 5.02 (95% CI, 2.93 to 8.60) and negative likelihood ratio of 0.42 (95% CI, 0.30 to 0.59).
	ImmunoCyt™: sensitivity and specificity	Moderate	Sensitivity was 0.78 (95% CI, 0.68 to 0.85) and specificity 0.78 (95% CI, 0.72 to 0.82), based on 14 studies, for a positive likelihood ratio of 3.49 (95% CI, 2.82 to 4.32) and negative likelihood ratio of 0.29 (95% CI, 0.20 to 0.41).
	CxBladder™: sensitivity and specificity	Low	Sensitivity was 0.82 (95% CI, 0.70 to 0.90) and specificity 0.85 (95% CI, 0.81 to 0.88) for evaluation of symptoms, based on 1 study, for a positive likelihood ratio of 5.53 (95% CI, 4.28 to 7.15) and negative likelihood ratio of 0.21 (95% CI, 0.13 to 0.36).

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Quantitative NMP22 versus qualitative BTA: sensitivity and specificity	Moderate	Based on 7 studies, there was no difference between quantitative NMP22 (cutoff >10 U/mL) and qualitative BTA in sensitivity (0.69; 95% CI, 0.62 to 0.76 vs. 0.66; 95% CI, 0.59 to 0.73, for a difference of 0.03; 95% CI, -0.04 to 0.10) or specificity (0.73; 95% CI, 0.62 to 0.82 vs. 0.76; 95% CI, 0.66 to 0.84, for a difference of 0.03; 95% CI, -0.08 to 0.01).
	ImmunoCyt versus FISH: sensitivity vs. specificity	Low	ImmunoCyt was associated with higher sensitivity than FISH (0.71; 95% CI, 0.54 to 0.84 vs. 0.61; 95% CI, 0.43 to 0.76, for a difference of 0.11; 95% CI, 0.001 to 0.21) but lower specificity (0.71; 95% CI, 0.62 to 0.79 vs. 0.79; 95% CI, 0.71 to 0.85, for a difference of -0.08; 95% CI, -0.15 to -0.001), based on 3 studies.
	Other head-to-head comparisons of urinary biomarkers	Insufficient	Evidence for other head-to-head comparisons of urinary biomarkers was based on small numbers of studies with imprecise estimates and methodological shortcomings, precluding reliable conclusions regarding comparative test performance.
	Various urinary biomarkers plus cytology vs. the urinary biomarker alone: sensitivity and specificity	Moderate	Sixteen studies found various urinary biomarkers plus cytology to be associated with higher sensitivity than the urinary biomarker alone (0.81; 95% CI, 0.75 to 0.86 vs. 0.69; 95% CI, 0.61 to 0.76, for a difference of 0.13; 95% CI, 0.08 to 0.17), with no difference in specificity.
Key Question 1a. Does the diagnostic accuracy differ according to patient characteristics (e.g., age, sex, race/ethnicity), or according to the nature of the presenting signs or symptoms?	Effects of tumor stage: sensitivity	High	Across urinary biomarkers, sensitivity increased with higher tumor stage. Evidence was most robust for quantitative NMP22 (11 studies), qualitative BTA (18 studies), and FISH (8 studies); the association between higher tumor stage and increased sensitivity was least pronounced for ImmunoCyt (10 studies). Sensitivity was generally similar to or slightly lower for CIS tumors than for T1 tumors.

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Effects of tumor grade: sensitivity	High	Across urinary biomarkers, sensitivity increased with higher tumor grade. Evidence was most robust for quantitative NMP22 (12 studies), ImmunoCyt (10 studies), qualitative BTA (18 studies), and FISH (9 studies).
	Effects of tumor size: sensitivity	Low	Two studies found that sensitivity was higher for larger (>1 cm or >2 cm) vs. smaller tumors.
	Effects of patient characteristics (age, sex, smoking status, and presence of other clinical conditions): sensitivity and specificity	Low	Evidence on the effects of patient characteristics, such as age, sex, smoking status, and presence of other clinical conditions, on diagnostic accuracy of urinary biomarkers was limited but did not clearly or consistently indicate effects on sensitivity or specificity.
Key Question 2. For patients with non–muscle-invasive bladder cancer, does the use of a formal risk-adapted assessment approach to treatment decisions (e.g., Guidelines of the European Association of Urology or based on urinary biomarker tests) decrease mortality or improve other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with treatment not guided by a formal assessed risk-adapted approach?	Mortality, recurrence, progression, need for cystectomy, quality of life	Insufficient	No studies.
Key Question 3. For patients with non–muscle-invasive bladder cancer treated with transurethral resection of bladder tumor (TURBT), what is the effectiveness of various intravesical chemotherapeutic or immunotherapeutic agents for decreasing mortality or improving other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with TURBT alone?	<i>BCG vs. no intravesical therapy</i> : All-cause mortality	Insufficient	No trial evaluated effects of BCG vs. no intravesical therapy on risk of all-cause mortality..
	<i>BCG vs. no intravesical therapy</i> : Bladder cancer specific mortality	Insufficient	One trial found BCG to be associated with decreased risk of bladder cancer specific mortality vs. no intravesical therapy, but the difference was not statistically significant (RR, 0.62; 95% CI, 0.32 to 1.19).
	<i>BCG vs. no intravesical therapy</i> : Recurrence	Low	BCG was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy (3 trials; RR, 0.56; 95% CI, 0.43 to 0.71; $I^2 = 0\%$ ).
	<i>BCG vs. no intravesical therapy</i> : Progression	Low	BCG was associated with decreased risk of bladder cancer progression (4 trials; RR, 0.39; 95% CI, 0.24 to 0.64; $I^2 = 40\%$ ) vs. no intravesical therapy

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>MMC vs. no intravesical therapy</i> : All-cause mortality	Low	There was no difference in risk of all cause-mortality for MMC vs. no intravesical therapy (1 trial; HR, 1.17; 95% CI, 0.89 to 1.53).
	<i>MMC vs. no intravesical therapy</i> : Bladder cancer specific mortality	Low	The effects on bladder cancer specific mortality were not statistically significant for MMC vs. no intravesical therapy (1 trial; HR, 0.71; 95% CI, 0.34 to 1.46).
	<i>MMC vs. no intravesical therapy</i> : Recurrence	Moderate	MMC was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy (8 trials; RR, 0.71; 95% CI, 0.57 to 0.89; $I^2 = 72\%$ ).
	<i>MMC vs. no intravesical therapy</i> : Progression	Low	Effects of MMC on bladder cancer progression were not statistically significant (5 trials; RR, 0.68; 95% CI, 0.39 to 1.20; $I^2 = 0\%$ ) vs. no intravesical therapy.
	<i>Doxorubicin vs. no intravesical therapy</i> : All-cause mortality	Low	Doxorubicin was associated with no clear effects on all-cause mortality (2 trials) vs. no intravesical therapy.
	<i>Doxorubicin vs. no intravesical therapy</i> : Bladder cancer specific mortality	Low	Doxorubicin was associated with no clear effects on bladder cancer specific mortality (1 trial) vs. no intravesical therapy.
	<i>Doxorubicin vs. no intravesical therapy</i> : Recurrence	Moderate	Doxorubicin was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy (10 trials; RR, 0.80; 95% CI, 0.72 to 0.88; $I^2 = 46\%$ ).
	<i>Doxorubicin vs. no intravesical therapy</i> : Progression	Low	Doxorubicin was associated with no difference in risk of bladder cancer progression (5 trials; RR, 1.03; 95% CI, 0.72 to 1.46; $I^2 = 0.0\%$ ) vs. no intravesical therapy.
	<i>Epirubicin vs. no intravesical therapy</i> : Recurrence	Moderate	Epirubicin was associated with decreased risk of bladder cancer recurrence (9 trials; RR, 0.63; 95% CI, 0.53 to 0.75; $I^2 = 64\%$ ) vs. no intravesical therapy.
	<i>Epirubicin vs. no intravesical therapy</i> : Progression	Low	Epirubicin was associated with a non-statistically significant effect on bladder cancer progression (8 trials; RR, 0.79; 95% CI, 0.84 to 1.30; $I^2 = 27\%$ ).
	<i>Gemcitabine vs. no intravesical therapy</i> : All-cause mortality, bladder cancer specific mortality, progression	Insufficient	Estimates for progression (RR, 3.00; 95% CI, 0.32 to 28.4), all-cause mortality (RR, 0.50; 95% CI, 0.13 to 2.00), and bladder cancer specific mortality (RR, 1.00; 95% CI, 0.06 to 15.81) were very imprecise for gemcitabine vs. no intravesical therapy.

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>Gemcitabine vs. no intravesical therapy</i> : Recurrence	Low	One trial found no difference between single-instillation gemcitabine vs. no intravesical therapy in risk of bladder cancer recurrence (RR, 0.98; 95% CI, 0.70 to 1.36).
	<i>Interferon alpha vs. no intravesical therapy</i> : Bladder cancer specific mortality	Low	Interferon alpha was associated with no difference in risk of bladder cancer specific mortality (1 trial; RR, 1.00; 95% CI, 0.15 to 6.75).
	<i>Interferon alpha vs. no intravesical therapy</i> : Recurrence	Low	Interferon alpha was associated with a non-statistically significant reduction in risk for bladder cancer recurrence vs. no intravesical therapy (3 trials; RR, 0.75; 95% CI, 0.53 to 1.06; $I^2 = 50\%$ ).
	<i>Interferon alpha vs. no intravesical therapy</i> : Progression	Low	Interferon alpha was associated with decreased risk of bladder cancer progression vs. no intravesical therapy (2 trials; RR, 0.33; 95% CI, 0.14 to 0.76; $I^2 = 0\%$ ).
	<i>Interferon gamma vs. no intravesical therapy</i> : Recurrence	Low	Interferon gamma was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy (1 trial; RR, 0.72; 95% CI, 0.51 to 1.01).
	<i>Interferon gamma vs. no intravesical therapy</i> : Progression	Low	Interferon gamma was associated with no difference in risk of bladder cancer progression vs. no intravesical therapy (1 trial; RR, 1.08; 95% CI, 0.07 to 16.4).
	<i>Thiotepa vs. no intravesical therapy</i> : Recurrence	Low	Thiotepa was associated with decreased risk of bladder cancer recurrence vs. no intravesical therapy in 5 trials (RR, 0.78; 95% CI, 0.58 to 1.06; $I^2 = 69\%$ ).
Key Question 3a. What is the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents, as monotherapy or in combination?	<i>BCG vs. MMC</i> : All-cause mortality	Moderate	There was no difference in risk of all-cause mortality between BCG and MMC (7 trials; RR, 0.94; 95% CI, 0.83 to 1.06; $I^2 = 0\%$ ).
	<i>BCG vs. MMC</i> : Bladder cancer specific mortality	Moderate	There was no difference between BCG and MMC in risk of bladder cancer specific mortality (5 trials; RR, 0.77; 95% CI, 0.54 to 1.10; $I^2 = 0\%$ ).
	<i>BCG vs. MMC</i> : Recurrence	Low	There were no differences between BCG and MMC in risk of bladder cancer recurrence (10 trials; RR, 0.95; 95% CI, 0.81 to 1.11; $I^2 = 67\%$ ).
	<i>BCG vs. MMC</i> : Progression	Moderate	There was no difference in risk of progression (7 trials; RR, 0.88; 95% CI, 0.66 to 1.17; $I^2 = 18\%$ ).

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG alone vs. BCG plus MMC given sequentially:</i> All-cause mortality, bladder cancer specific mortality, recurrence, progression	Low	There were no differences sequentially in risk of all-cause (1 trial; RR, 1.57; 95% CI, 0.67 to 3.71) or bladder cancer specific mortality (2 trials; RR, 1.10; 95% CI, 0.50 to 2.38; $I^2 = 17\%$ ), bladder cancer recurrence (4 trials; RR, 1.03; 95% CI, 0.70 to 1.52; $I^2 = 75\%$ ), progression (3 trials; RR, 0.87; 95% CI, 0.40 to 1.91; $I^2 = 22\%$ ), or cystectomy (4 trials; RR, 0.87; 95% CI, 0.41 to 1.84; $I^2 = 0\%$ ).
	<i>BCG plus MMC given sequentially vs. MMC alone:</i> All-cause mortality, bladder cancer specific mortality, recurrence, progression	Low	There were no differences in risk of all-cause (2 trials; RR, 1.53; 95% CI, 0.72 to 1.74 and RR, 0.95; 95% CI, 0.71 to 1.30) or bladder cancer mortality (2 trials; RR, 0.64; 95% CI, 0.22 to 1.88 and RR, 0.95; 95% CI, 0.45 to 1.56), bladder cancer recurrence (2 trials; RR, 0.88; 95% CI, 0.75 to 1.03; $I^2 = 0\%$ ), or progression (2 trials; RR, 0.82; 95% CI, 0.40 to 1.68 and RR, 1.28; 95% CI, 0.35 to 4.61).
	<i>BCG vs. doxorubicin:</i> All-cause mortality, recurrence, progression	Low	BCG was associated with decreased risk of bladder cancer recurrence vs. doxorubicin (2 trials; RR, 0.31; 95% CI, 0.16 to 0.61 and RR, 0.75; 95% CI, 0.64 to 0.88), but there was no difference in risk of all-cause mortality (2 trials; RR, 0.40; 95% CI, 0.01 to 12 and RR, 1.00; 95% CI, 0.71 to 1.37) or bladder cancer progression (1 trial; RR, 0.20; 95% CI, 0.02 to 1.72).
	<i>BCG vs. epirubicin:</i> All-cause mortality	Low	Estimates favored BCG for all-cause mortality, but differences were not statistically significant (3 trials; RR, 0.72; 95% CI, 0.44 to 1.19; $I^2 = 87\%$ ).
	<i>BCG vs. epirubicin:</i> Bladder cancer specific mortality	Low	Estimates favored BCG for bladder cancer specific mortality, but differences were not statistically significant (3 trials; RR, 0.72; 95% CI, 0.25 to 2.08; $I^2 = 80\%$ ).
	<i>BCG vs. epirubicin:</i> Recurrence	Moderate	BCG was associated with reduced risk of bladder cancer recurrence, but statistical heterogeneity was high (5 trials; RR, 0.54; 95% CI, 0.40 to 0.74; $I^2 = 76\%$ ).

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG vs. epirubicin:</i> Progression	Low	Estimates favored BCG for bladder cancer progression, but differences were not statistically significant (5 trials; RR, 0.60; 95% CI, 0.36 to 1.01; $I^2 = 47\%$ ).
	<i>BCG alone vs. BCG plus epirubicin given sequentially:</i> Recurrence, progression	Low	There were no differences in risk of bladder cancer recurrence (3 trials; RR, 1.25; 95% CI, 0.92 to 1.69; $I^2 = 0\%$ ). BCG was associated with increased risk of bladder cancer progression, but the difference was not statistically significant (3 trials; RR, 1.92; 95% CI, 0.73 to 5.07; $I^2 = 0\%$ ).
	<i>BCG vs. epirubicin plus interferon:</i> Bladder cancer specific mortality, progression	Low	One trial found no differences in risk of bladder cancer mortality (RR, 0.79; 95% CI, 0.32 to 1.63) or progression-free survival, although BCG was associated with decreased risk of bladder cancer recurrence (RR, 0.66; 95% CI, 0.51 to 0.85).
	<i>BCG vs. gemcitabine:</i> All-cause mortality	Low	There were no differences in risk of all-cause mortality (1 trial; RR, 1.20; 95% CI, 0.04 to 34).
	<i>BCG vs. gemcitabine:</i> Recurrence	Insufficient	Evidence from 3 trials was insufficient to determine risk of bladder cancer recurrence because of clinical heterogeneity and inconsistent findings (RR, 1.67; 95% CI, 1.21 to 2.29; RR, 0.53; 95% CI, 0.28 to 1.01; and RR, 0.76; 95% CI, 0.44 to 1.90).
	<i>BCG vs. gemcitabine:</i> Progression	Low	There were no differences in risk of progression (2 trials; RR, 1.11; 95% CI, 0.53 to 2.34 and RR, 0.52; 95% CI, 0.13 to 2.06).
	<i>BCG vs. gemcitabine:</i> Quality of life	Low	There were no differences for BCG vs. gemcitabine in quality of life (1 trial).
	<i>BCG alone vs. BCG plus gemcitabine given sequentially:</i> Recurrence, progression	Low	There were no differences in risk of bladder cancer recurrence (1 trial; RR, 0.86; 95% CI, 0.49 to 1.51) or progression (1 trial; RR, 1.18; 95% CI, 0.30 to 4.61).
	<i>BCG vs. interferon alpha-2a:</i> Recurrence, progression	Low	BCG was associated with reduced risk of bladder cancer recurrence (1 trial; RR, 0.57; 95% CI, 0.39 to 0.82), but the difference in risk of bladder cancer progression was not statistically significant (1 trial; RR, 0.69; 95% CI, 0.25 to 1.92).

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG alone vs. alternating BCG and interferon alpha-2b:</i> Recurrence	Low	BCG alone was associated with reduced risk of bladder cancer recurrence (1 trial; RR, 0.42; 95% CI, 0.30 to 0.59).
	<i>BCG alone vs. coadministration of BCG and interferon alpha-2b:</i> Recurrence, progression	Low	Differences in risk of bladder cancer recurrence (1 trial; RR, 0.88; 95% CI, 0.71 to 1.08) or progression (1 trial; RR, 0.76; 95% CI, 0.17 to 3.30) did not reach statistical significance.
	<i>BCG vs. thiotepa:</i> Recurrence	Low	Two trials found maintenance therapy with BCG to be associated with decreased risk of recurrence vs. thiotepa (RR, 0.38; 95% CI, 0.19 to 0.76 and RR, 0.04; 95% CI, 0.00 to 0.63).
	<i>BCG vs. thiotepa:</i> Progression, mortality, and cystectomy	Insufficient	Estimates were too imprecise to evaluate effects.
	<i>MMC vs. doxorubicin:</i> Recurrence, progression	Low	There was no difference in risk of bladder cancer recurrence (6 trials; RR, 1.00; 95% CI, 0.82 to 1.22; $I^2 = 44\%$ ), but MMC was associated with a non-statistically significant trend toward decreased risk of bladder cancer progression (4 trials; RR, 0.63; 95% CI, 0.37 to 1.08; $I^2 = 21\%$ ).
	<i>MMC vs. epirubicin:</i> Recurrence	Low	There was no difference in risk of bladder cancer recurrence in 1 trial (RR, 1.16; 95% CI, 0.52 to 2.58).
	<i>MMC vs. gemcitabine:</i> Recurrence, progression	Low	In 1 trial, there was no difference in risk of bladder cancer progression ( $p = 0.29$ ). MMC was associated with increased risk of recurrence, but the difference was not statistically significant (RR, 1.64; 95% CI, 0.64 to 4.19).
	<i>MMC vs. interferon alpha:</i> Recurrence, progression	Low	One trial found no difference between MMC and interferon alpha in risk of bladder cancer recurrence (RR, 0.77; 95% CI, 0.58 to 1.01) or bladder cancer progression (RR, 1.38; 95% CI, 0.49 to 3.88).
	<i>MMC vs. interferon gamma:</i> Recurrence	Low	MMC was associated with increased risk of bladder cancer recurrence in 1 trial (RR, 1.61; 95% CI, 0.97 to 2.67).
	<i>MMC vs. thiotepa:</i> Recurrence	Low	Two trials found no difference between MMC and thiotepa in risk of recurrence (RR, 1.76; 95% CI, 0.36 to 8.70 and RR, 1.14; 95% CI, 0.60 to 2.16).

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>Doxorubicin vs. epirubicin:</i> Recurrence, progression	Low	Doxorubicin was associated with increased risk of bladder cancer recurrence (3 trials; RR, 1.56; 95% CI, 1.08 to 2.22; $I^2 = 0\%$ ); the difference in risk of progression was not statistically significant (1 trial; RR, 1.32; 95% CI, 0.50 to 3.47).
	<i>Doxorubicin vs. thiotepa:</i> Recurrence	Low	There was no statistically significant difference in risk of bladder cancer recurrence (RR, 1.22; 95% CI, 0.76 to 1.94).
	<i>Doxorubicin vs. thiotepa:</i> Progression, noncancer mortality, cancer specific mortality	Insufficient	Estimates from 1 trial for progression (RR, 2.11; 95% CI, 0.40 to 11.06), noncancer mortality (RR, 0.35; 95% CI, 0.01 to 8.45), and cancer specific mortality (RR, 3.17; 95% CI, 0.13 to 76.1) were very imprecise.
	<i>Epirubicin vs. interferon alpha:</i> Recurrence	Low	Epirubicin was associated with decreased risk of bladder cancer recurrence in 1 trial (RR, 0.67; 95% CI, 0.49 to 0.91).
Key Question 3b. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers?	Stage, grade, tumor multiplicity, primary vs. recurrent	Low	There were no clear differences in estimates of effectiveness of intravesical therapies in subgroups defined by tumor stage, grade, size, multiplicity, recurrence status, or DNA ploidy
Key Question 3c. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities?	Age, sex, race/ethnicity, performance status, comorbidities	Insufficient	No studies.
	Recurrence, disease-free survival	Low	In patients with recurrence or progression following prior BCG therapy, 1 trial found maintenance therapy with gemcitabine to be associated with decreased risk of recurrence vs. repeat treatment with BCG, and 1 trial found MMC maintenance therapy to be associated with lower likelihood of disease-free survival than gemcitabine; estimates for progression were imprecise.
Key Question 3d. Does the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents differ according to dosing frequency, duration of treatment, and/or the timing of administration relative to TURBT?	Standard vs. lower dose BCG: recurrence, progression, mortality, adverse events	Low	Six trials found no clear differences in risk of recurrence, progression, or bladder cancer mortality, including in patients with higher risk NMIBC, although there was some inconsistency between trials. Standard therapy was associated with increased risk of local and systemic adverse events vs. lower dose BCG.

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Maintenance vs. induction BCG: recurrence, progression, adverse events	Low	Two trials found more prolonged courses of BCG to be associated with decreased risk of bladder cancer recurrence vs. induction therapy in patients with higher risk NMIBC (RR, 0.54; 95% CI, 0.31 to 0.95) but increased risk of adverse events.
	BCG maintenance for 1 vs. 3 years: recurrence, progression, mortality, adverse events	Low	One trial of patients with solitary T1Grade(G)3 or multiple Ta–T1/G1–G3 tumors found no difference between 1 vs. 3 years of BCG maintenance therapy in risk of recurrence, progression, mortality, or adverse events.
	MMC single vs. 5 instillations: recurrence, progression, mortality, adverse events	Low	One trial of patients with NMIBC (not selected for being at higher risk) found no clear differences in risk of recurrence, progression, or mortality. The single instillation was associated with lower risk of local adverse events.
	MMC induction vs. maintenance: recurrence, adverse events	Low	One trial of patients with higher risk NMIBC found MMC 20 mg induction therapy for 6 weeks to be associated with higher risk of recurrence than maintenance therapy. There were no clear differences in risk of adverse events.
	MMC maintenance therapy with increased frequency and number of instillations vs. fewer instillations: recurrence, progression, adverse events	Low	Two trials of MMC maintenance regimens in patients with NMIBC not selected for being at higher risk found some evidence that a higher total number of instillations and increased frequency during initial therapy were associated with lower risk of recurrence and progression, and might be associated with lower risk of local adverse events.
	MMC optimized through alkalinization of urine vs. nonoptimized administration: recurrence, adverse events	Low	One trial found no difference between “optimized” versus nonoptimized administration of intravesical MMC in risk of recurrence in patients with low-risk NMIBC, but 1 other trial of patients with higher risk NMIBC found optimized administration to be associated with lower risk of recurrence and increased risk of local adverse events.

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Doxorubicin 8 weeks vs. 2 years: recurrence, progression, adverse events	Low	Two trials of patients with NMIBC not selected for being at higher risk found no differences between doxorubicin 30 mg and 20 mg given as short (8 weeks) or long (2 years) regimens in risk of recurrence or progression, with no differences in adverse events.
	Doxorubicin induction vs. maintenance: recurrence, progression, mortality, adverse events	Low	Two trials of patients with NMIBC not selected for being at higher risk found no clear differences between doxorubicin induction therapy and induction plus maintenance in risk of recurrence, progression, or mortality, with no differences in adverse events.
	Doxorubicin prior to vs. after TURBT: recurrence, adverse events	Low	Two trials of doxorubicin found no clear benefits associated with administration prior to TURBT or multiple instillations immediately after TURBT, with some evidence of increased adverse events with multiple immediate post-TURBT instillations.
	Epirubicin higher vs. lower doses: recurrence, progression, adverse events	Moderate	Three trials of epirubicin found no clear evidence that higher doses are associated with reduced risk of recurrence or progression vs. lower doses, with no differences in adverse events.
	Epirubicin single vs. multiple instillations: recurrence, progression, bladder cancer mortality, adverse events	Moderate	Three trials found no clear difference between single-instillation epirubicin and multiple instillations in patients with low- or high-risk NMIBC in risk of recurrence, progression, or bladder cancer mortality, with some evidence of lower risk of local adverse events with single instillation.
	Epirubicin maintenance vs. induction without maintenance: recurrence, progression, adverse events	Moderate	Two trials found no clear differences between epirubicin maintenance therapy and induction without maintenance in risk of recurrence or progression, including 1 trial of patients with higher risk NMIBC. There were no differences in risk of local adverse events.

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	Epirubicin, more vs. less intensive therapy: recurrence, adverse events	Low	Five trials that evaluated different epirubicin regimens that included maintenance therapy found some evidence that more intensive therapy is associated with decreased risk of recurrence, but results were inconsistent. There was no difference in risk of adverse events.
	Thiotepa 30 vs. 60 mg: recurrence, adverse events	Low	Two trials found no clear differences between thiotepa 30 mg and 60 mg for maintenance or for treatment of incompletely resected NMIBC or CIS.
	Interferon alpha-2b, high vs. lower doses: recurrence, progression, resolution of bladder cancer marker lesions	Low	Three trials found higher doses of interferon alpha-2b to be associated with improved outcomes related to recurrence, progression, or resolution of bladder cancer marker lesions vs. lower doses, but most estimates were imprecise and did not reach statistical significance. There were no clear differences in risk of local or systemic adverse events.
	MMC or doxorubicin on day of TURBT vs. 1 to 2 weeks after TURBT: recurrence, progression, mortality, adverse events	Low	One trial found no difference between initiation of intravesical therapy (9 instillations over 6 months) with MMC or doxorubicin 50 mg on the day of TURBT versus 1 to 2 weeks after TURBT in risk of recurrence, progression, or mortality.
	MMC or doxorubicin maintenance vs. no maintenance: recurrence, progression, mortality, adverse events	Low	One trial found no difference between maintenance beyond 6 months vs. no additional maintenance therapy. There were no clear differences in local or systemic adverse events.
Key Question 4. For patients with high risk non--muscle-invasive bladder cancer treated with TURBT, what is the effectiveness of external beam radiation therapy (either alone or with systemic chemotherapy/immunotherapy) for decreasing mortality or improving other outcomes compared with intravesical chemotherapy/immunotherapy alone or cystectomy?	Mortality, recurrence, progression	Low	One randomized trial of patients with T1G3 bladder cancer found no effects of radiation therapy vs. no radiotherapy (for unifocal disease and no CIS) or radiation therapy vs. intravesical therapy (for multifocal disease or CIS) in recurrence-free survival (HR, 0.94; 95% CI, 0.67 to 1.30), progression-free interval (HR, 1.07; 95% CI, 0.65 to 1.74), progression-free survival (HR, 1.35; 95% CI, 0.92 to 1.98), or overall survival (HR, 1.32; 95% CI, 0.86 to 2.04) after 5 years.

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
Key Question 5. In surveillance of patients treated for non–muscle-invasive bladder cancer, what is the effectiveness of various urinary biomarkers to decrease mortality or improve other outcomes compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging)?	Mortality	Insufficient	No studies.
Key Question 5a. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers?		Insufficient	No studies.
Key Question 5b. Does the comparative effectiveness differ according to the treatment used (i.e., specific chemotherapeutic or immunotherapeutic agents and/or TURBT)?		Insufficient	No studies.
Key Question 5c. Does the comparative effectiveness differ according to the length of surveillance intervals?		Insufficient	No studies.
Key Question 5d. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, or race/ethnicity?		Insufficient	No studies.

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
Key Question 6. For initial diagnosis or surveillance of patients treated for non-muscle-invasive bladder cancer, what is the effectiveness of blue light or other methods of augmented cystoscopy compared with standard cystoscopy for recurrence rates, progression of bladder cancer, mortality, or other clinical outcomes?	<i>Fluorescent cystoscopy vs. white light cystoscopy: Mortality</i>	Low	There was no difference between fluorescent and white light cystoscopy in risk of mortality (3 trials; RR, 1.28; 95% CI, 0.55 to 2.95; $I^2 = 41\%$ ).
	<i>Fluorescent cystoscopy vs. white light cystoscopy: Recurrence</i>	Low	Fluorescent cystoscopy with 5-ALA or HAL was associated with decreased risk of bladder cancer recurrence vs. white light cystoscopy at short-term (<3 months; 9 trials, RR 0.58, 95% CI 0.36 to 0.94, $I^2=75\%$ ), intermediate-term (3 months to <1 year, 5 trials, RR 0.67, 95% CI 0.51 to 0.88, $I^2=35\%$ ), and long-term followup ( $\geq 1$ year, 11 trials, RR 0.81, 95% CI 0.68 to 0.98, $I^2=64\%$ ), but findings were inconsistent and potentially susceptible to performance bias (because of failure to blind the initial cystoscopy) and publication bias.
	<i>Fluorescent cystoscopy vs. white light cystoscopy: Progression</i>	Moderate	There was no difference between fluorescent and white light cystoscopy in risk of progression to muscle-invasive bladder cancer (9 trials; RR, 0.78; 95% CI, 0.55 to 1.12; $I^2 = 0\%$ ).
	<i>Narrow band imaging vs. white light cystoscopy: Recurrence</i>	Low	Narrow band imaging was associated with lower risk of bladder cancer recurrence at 3 months (3.9% vs. 17%; OR, 0.62; 95% CI, 0.41 to 0.92) and at 12 months (OR, 0.24; 95% CI, 0.07 to 0.81) in 1 trial.
Key Question 7. What are the comparative adverse effects of various tests for diagnosis and post-treatment surveillance of bladder cancer, including urinary biomarkers, cytology, and cystoscopy?	Urinary biomarkers: adverse clinical outcomes	Insufficient	Urinary biomarkers miss 23% to 42% of patients with bladder cancer and are incorrectly positive in 11% to 28% of patients without bladder cancer, but no study directly measured effects of inaccurate diagnosis on clinical outcomes.
	Fluorescent vs. white light cystoscopy: false-positives	Low	There were no clear differences between fluorescent cystoscopy and white light cystoscopy in risk of false-positives in 2 trials.
	Fluorescent vs. white light cystoscopy: renal and genitourinary adverse events	Low	There were no clear differences between fluorescent cystoscopy and white light cystoscopy in risk of renal and genitourinary adverse events in 2 trials.

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
Key Question 8. What are the comparative adverse effects of various treatments for non--muscle-invasive bladder cancer, including intravesical chemotherapeutic or immunotherapeutic agents and TURBT?	BCG vs. no intravesical therapy: local and systemic adverse events	Low	Four trials reported granulomatous cystitis or irritative symptoms in 27% to 84% of patients, macroscopic hematuria in 21% to 72%, and fever in 27% to 44%. Harms were not reported in patients who did not receive intravesical therapy.
	Non-BCG intravesical therapies vs. no intravesical therapy: local and systemic adverse events	Low (local adverse events); insufficient (systemic adverse events)	Evidence on harms was very limited, although some trials reported an increased risk of local adverse events. Evidence was insufficient to determine effects of non-BCG intravesical therapies vs. no intravesical therapy on risk of systemic adverse events.
	<i>BCG</i> vs. <i>MMC</i> : Local adverse events	Low (moderate for cystitis and hematuria)	BCG was associated with increased risk of any local adverse event (2 trials; RR, 2.01; 95% CI, 1.59 to 2.54; $I^2 = 0\%$ ), granulomatous cystitis (5 trials; RR, 1.71; 95% CI, 1.22 to 2.41; $I^2 = 58\%$ ), dysuria (3 trials; 48% vs. 32%; RR, 1.23; 95% CI, 1.03 to 1.46; $I^2 = 34\%$ ), and hematuria (6 trials; RR, 1.78; 95% CI, 1.24 to 2.56; $I^2 = 62\%$ ) vs. MMC.
	<i>BCG</i> vs. <i>MMC</i> : Systemic adverse events	Low	BCG was associated with increased risk of any systemic adverse event (2 trials; RR, 2.01; 95% CI, 1.59 to 2.54; $I^2 = 0\%$ ) and fever (4 trials; RR, 4.51; 95% CI, 2.31 to 8.82; $I^2 = 25\%$ ) vs. MMC.
	<i>BCG</i> alone vs. <i>BCG</i> plus <i>MMC</i> given sequentially: Discontinuation of therapy	Low	BCG alone was associated with increased risk of discontinuation of instillations vs. BCG plus MMC given sequentially (1 trial; RR, 4.06; 95% CI, 2.09 to 7.86).
	<i>BCG</i> plus <i>MMC</i> given sequentially vs. <i>MMC</i> alone: Local adverse events	Low	There was no difference between sequentially administered BCG plus MMC and MMC alone in local adverse events (1 trial; RR, 1.36; 95% CI, 0.60 to 3.08) or risk of granulomatous cystitis (1 trial; RR, 1.30; 95% CI, 0.88 to 1.93).
	<i>BCG</i> plus <i>MMC</i> given sequentially vs. <i>MMC</i> alone: Systemic adverse events	Low	There was no difference between BCG and MMC given sequentially and MMC used alone in systemic adverse events (1 trial; RR, 1.07; 95% CI, 0.63 to 1.84), but BCG plus MMC was associated with increased risk of fever (1 trial; 12% vs. 3%; RR, 3.75; 95% CI, 1.08 to 13).

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG plus MMC given sequentially vs. MMC alone:</i> Discontinuation of therapy	Low	There was no difference between alternating BCG plus MMC and MMC alone in risk of discontinuation of instillations in patients with CIS (1 trial; RR, 0.54; 95% CI, 0.16 to 1.84) or in patients with Ta or T1 tumors (1 trial; RR, 0.93; 95% CI, 0.52 to 1.65).
	<i>BCG vs. doxorubicin:</i> Local adverse events	Low (cystitis); insufficient (dysuria and hematuria)	BCG was associated with increased risk of cystitis vs. doxorubicin (1 trial; RR, 17; 95% CI, 1 to 289), but there was insufficient evidence to determine effects on dysuria (3 trials; data not pooled) and hematuria (2 trials; data not pooled) because of small numbers of trials with inconsistent results.
	<i>BCG vs. epirubicin:</i> Local adverse events	Low	BCG was associated with increased risk of local side effects (1 trial; RR, 3.28; 95% CI, 1.26 to 8.53).
	<i>BCG vs. epirubicin:</i> Discontinuation of therapy	Insufficient	Results were mixed for discontinuation of intravesical therapy (2 trials; data not pooled).
	<i>BCG vs. epirubicin:</i> Systemic adverse events	Low	BCG was associated with increased risk of granulomatous cystitis (4 trials; RR, 1.86; 95% CI, 1.35 to 2.56; $I^2 = 65\%$ ), dysuria (1 trial; RR, 2.43; 95% CI, 1.13 to 5.24), hematuria (4 trials; RR, 1.77; 95% CI, 1.41 to 2.22; $I^2 = 0\%$ ), and fever (2 trials; RR, 9.73; 95% CI, 2.72 to 35; $I^2 = 0\%$ ).
	<i>BCG alone vs. BCG plus epirubicin given sequentially:</i> Local adverse events	Low	There was no difference in risk of dysuria (1 trial; RR, 1.22; 95% CI, 0.56 to 2.66) or hematuria (2 trials; RR, 2.27; 95% CI, 0.86 to 6.00; $I^2 = 0\%$ ).
	<i>BCG alone vs. BCG plus epirubicin given sequentially:</i> Systemic adverse events	Low	BCG was associated with increased risk of systemic adverse events (1 trial; RR, 5.97; 95% CI, 2.18 to 16) and granulomatous cystitis (1 trial; RR, 2.28; 95% CI, 1.46 to 3.54) but no difference in risk of fever (2 trials; RR, 2.09; 95% CI, 0.48 to 9.02; $I^2 = 0\%$ ).
	<i>BCG alone vs. BCG plus epirubicin given sequentially:</i> Discontinuation of therapy	Low	BCG was associated with increased risk of discontinuation of instillations (1 trial; RR, 4.56; 95% CI, 1.35 to 15).

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>BCG vs. gemcitabine</i> : Local adverse events	Low	There were no differences between BCG and gemcitabine in risk of local adverse events requiring postponement or discontinuation of intravesical therapy (1 trial; RR, 1.33; 95% CI, 0.32 to 5.49).
	<i>BCG vs. gemcitabine</i> : Systemic adverse events	Low	There were no differences in systemic adverse events (1 trial; RR, 0.50; 95% CI, 0.10 to 2.5), dysuria (2 trials; RR, 1.51; 95% CI, 0.92 to 2.50; $I^2 = 0\%$ ), or hematuria (2 trials; RR, 4.62; 95% CI, 0.78 to 27; $I^2 = 29\%$ ), but BCG was associated with increased risk of fever (2 trials; RR, 6.24; 95% CI, 1.03 to 38; $I^2 = 5\%$ ).
	<i>BCG alone vs. BCG plus gemcitabine given sequentially</i> : Local adverse events	Low	One trial found no difference in risk of dysuria (RR, 0.92; 95% CI, 0.52 to 1.65) or hematuria (RR, 0.30; 95% CI, 0.08 to 1.09).
	<i>BCG vs. interferon alpha-2a</i> : Local adverse events	Low	BCG was associated with increased risk of dysuria (1 trial; RR, 84; 95% CI, 5.29 to 1,319).
	<i>BCG vs. interferon alpha-2a</i> : Systemic adverse events	Low	There was no difference in risk of fever (1 trial; RR, 4.82; 95% CI, 0.25 to 94).
	<i>BCG alone vs. coadministration of BCG and interferon alpha-2b</i> : Systemic adverse events	Low	BCG was associated with increased risk of constitutional symptoms (1 trial; RR, 1.63; 95% CI, 1.12 to 2.38) and fever (1 trial; RR, 2.26; 95% CI, 1.30 to 3.95).
	<i>BCG vs. thiotepa</i> : Local adverse events	Low	BCG was associated with increased risk of bladder irritability (1 trial; RR, 2.93; 95% CI, 1.45 to 5.90) and cystitis (1 trial; RR, 18; 95% CI, 1.11 to 306).
	<i>BCG vs. thiotepa</i> : Systemic adverse events	Low	BCG was associated with increased risk of fever (1 trial; RR, 8.36; 95% CI, 0.47 to 150).
	<i>MMC vs. doxorubicin</i> : Local adverse events	Insufficient	Evidence was insufficient to determine effects of MMC vs. doxorubicin on risk of local adverse events, based on inconsistent results from 6 trials.
	<i>MMC vs. epirubicin</i> : Local adverse events	Low	One small trial found no difference between MMC and epirubicin 80 mg in risk of urinary symptoms.
	<i>MMC vs. interferon alpha</i> : Local adverse events	Low	One trial found MMC to be associated with greater risk of hematuria vs. interferon alpha (RR, 2.00; 95% CI, 1.09 to 3.65) and no difference in risk of dysuria or urinary frequency.

**Table 21. Summary of the strength of evidence (continued)**

Key Question	Outcome	Strength-of-Evidence Grade	Conclusion
	<i>MMC vs. interferon alpha</i> : Systemic adverse events	Low	One trial found MMC to be associated with decreased risk of fever (RR, 0.13; 95% CI, 0.03 to 0.55).
	<i>MMC vs. gemcitabine</i> : Local adverse events	Low	One trial found MMC to be associated with increased risk of chemical cystitis (RR, 3.93; 95% CI, 1.17 to 13.14), with no difference in risk of dysuria or hematuria.
	<i>Doxorubicin vs. epirubicin</i> : Local adverse events	Low	Doxorubicin was associated with increased risk of chemical cystitis (1 trial; RR, 1.85; 95% CI, 1.13 to 3.03), with no clear difference in risk of dysuria or urinary frequency (2 trials) or hematuria (3 trials; RR, 1.53; 95% CI, 0.50 to 4.66; $I^2 = 0\%$ ).
	<i>Doxorubicin vs. thiotepa</i> : Local adverse events	Low	One trial found no difference in risk of bladder irritability (RR, 0.92; 95% CI, 0.36 to 2.37).
	<i>Epirubicin vs. interferon alpha</i> : Local adverse events	Low	One trial found no difference in risk of dysuria.
	<i>Epirubicin vs. interferon alpha</i> : Systemic adverse events	Low	One trial found no difference in risk of fever.
Key Question 8a. How do adverse effects of treatment vary by patient characteristics, such as age, sex, race/ethnicity, performance status, or medical comorbidities such as chronic kidney disease?	Adverse effects	Insufficient	No studies

5-ALA = 5-aminolevulinic acid; BCG = bacillus Calmette–Guérin; BTA = bladder tumor antigen; CI = confidence interval; CIS = carcinoma in situ; FISH = fluorescence in situ hybridization; G1 = Grade 1; G3 = Grade 3; HAL = hexaminolevulinate; HR = hazard ratio; MMC = Mitomycin C; mg = milligram; NMP22 = nuclear matrix protein-22; NMIBC = non-muscle-invasive bladder cancer; OR = odds ratio; RR = risk ratio; T1 = Tumor stage 1; Ta = Tumor stage a; TURBT = transurethral resection of bladder tumor

**Table 22. Post-test probability of bladder cancer using different biomarkers**

Urinary Biomarker	Pretest Probability of Bladder Cancer	Positive Likelihood Ratio (95% CI)	Post-Test Probability of HCC Following a Positive Test	Negative Likelihood Ratio (95% CI)	Post-Test Probability of HCC Following a Negative Test
Quantitative NMP22	5%	3.05 (2.28 to 4.10)	14%	0.40 (0.32 to 0.50)	2.1%
	20%	3.05 (2.28 to 4.10)	43%	0.40 (0.32 to 0.50)	9.1%
Qualitative NMP22	5%	4.89 (3.23 to 7.40)	20%	0.48 (0.33 to 0.71)	2.5%
	20%	4.89 (3.23 to 7.40)	55%	0.48 (0.33 to 0.71)	11%
Qualitative BTA	5%	2.80 (2.31 to 3.39)	13%	0.47 (0.30 to 0.55)	2.4%
	20%	2.80 (2.31 to 3.39)	41%	0.47 (0.30 to 0.55)	11%
Quantitative BTA	5%	2.52 (1.86 to 3.41)	12%	0.47 (0.37 to 0.61)	2.4%
	20%	2.52 (1.86 to 3.41)	39%	0.47 (0.37 to 0.61)	11%
FISH	5%	5.02 (2.93 to 8.60)	21%	0.42 (0.30 to 0.59)	2.2%
	20%	5.02 (2.93 to 8.60)	56%	0.42 (0.30 to 0.59)	9.5%
ImmunoCyt™	5%	3.49 (2.82 to 4.32)	16%	0.29 (0.20 to 0.41)	1.5%
	20%	3.49 (2.82 to 4.32)	47%	0.29 (0.20 to 0.41)	6.8%

BTA = bladder tumor antigen; FISH = fluorescence in situ hybridization; HCC = hepatocellular carcinoma; NMP22 = nuclear matrix protein-22

## Conclusions

Urinary biomarkers are falsely negative in a substantial proportion of patients with bladder cancer and additional research is needed to clarify advantages of fluorescent cystoscopy over white light cystoscopy. Intravesical therapy reduces risk of bladder cancer recurrence versus no intravesical therapy. Bacillus Calmette-Guérin (BCG) is the only intravesical therapy shown to be associated with decreased risk of bladder cancer progression, but is associated with a high rate of adverse events.

TURBT	Transurethral resection of the bladder tumor
WHO	World Health Organization

# Emerging Approaches to Diagnosis and Treatment of Non-Muscle-Invasive Bladder Cancer: Addendum

This addendum details updated results for Key Question 3 (comparative effectiveness of intravesical therapies) and Key Question 6 (comparative effectiveness of fluorescent versus white light cystoscopy). An updated search using the same search strategy from the original report was conducted in September 2015. The methods used for this update were the same as in the original report.

## Key Question 3

We identified two additional trials (n=43 and 63) of adjuvant intravesical therapy versus TURBT alone.<sup>1,2</sup> One trial was rated medium risk of bias<sup>1</sup> and the other high risk of bias.<sup>2</sup> Both trials evaluated single dose therapy with MMC in patients with lower-risk NMIBC.

We updated the meta-analyses of MMC versus TURBT alone with the new trials. For recurrence, we also added data from a previously included trial that was omitted in the original report.<sup>3</sup> The only outcomes that were affected in the new analysis were bladder cancer recurrence and progression; updated estimates and conclusions were generally similar to those in the original report (Table 1).

**Table 1. Updated results for MMC versus no intravesical therapy (TURBT alone)**

Intravesical Therapy	All-Cause Mortality	Bladder Cancer-Specific Mortality	Bladder Cancer Recurrence	Bladder Cancer Progression
MMC	1 trial, HR 1.17, 95% CI 0.89 to 1.53	1 trial, HR 0.71, 95% CI 0.34 to 1.46	11 trials, RR 0.68, 95% CI 0.55 to 0.83, I <sup>2</sup> =74%	7 trials, RR 0.65, 95% CI 0.38 to 1.11, I <sup>2</sup> =0%

BCG = bacillus Calmette Guérin; CI = confidence interval; RR = relative risk; HR = hazard ratio

Regarding head-to-head comparisons of intravesical therapies, we identified one additional trial (n=407, medium risk of bias) of intravesical BCG versus BCG plus MMC given sequentially.<sup>4</sup> We updated the meta-analyses with the new study; we also added data on progression from a previously included trial<sup>5</sup> that was omitted from the original report. Updated estimates and conclusions were similar to those in the original report (Table 2)

**Table 2. Updated results for BCG versus BCG plus MMC given sequentially**

Comparison	All-Cause Mortality	Bladder Cancer-Specific Mortality	Bladder Cancer Recurrence	Bladder Cancer Progression
BCG vs. BCG plus MMC given sequentially	2 trials, RR 1.15, 95% CI 0.84 to 1.57, I <sup>2</sup> =0%	3 trials, RR 1.27, 95% CI 0.76 to 2.12, I <sup>2</sup> =0%	5 trials, RR 1.17, 95% CI 0.77 to 1.77, I <sup>2</sup> =77%	5 trials, RR 0.86, 95% CI 0.61 to 1.22, I <sup>2</sup> =0%

BCG = bacillus Calmette Guérin; CI = confidence interval; MMC = mitomycin C; RR = risk ratio

For comparisons involving dose or duration, we identified one additional trial (n=166, medium risk of bias) that compared BCG Tokyo strain 40 mg versus 80 mg (each administered once weekly for eight weeks).<sup>6</sup> It was consistent with two trials in the original report that found no clear difference between higher and lower doses of BCG. In the new trial, there was no clear

difference between the lower and higher dose in risk of complete response (78% vs. 85%,  $p=0.12$ ), recurrence-free survival ( $p=0.94$ ), or progression (6.2% vs. 5.8%).<sup>6</sup>

## Key Question 6

We identified one new trial ( $n=85$ , medium risk of bias) of fluorescent cystoscopy plus white light cystoscopy versus white light cystoscopy alone that reported effects on bladder cancer recurrence.<sup>7</sup> It found no clear difference between fluorescent plus white light cystoscopy versus white light cystoscopy alone in risk of recurrence through up to 40 months of follow-up (38% vs. 46%, RR 0.82, 95% CI 0.49 to 1.35), though results slightly favored fluorescent cystoscopy. All patients received a single instillation of epirubicin immediately following TURBT. There were also no differences between fluorescent versus white light cystoscopy when patients were stratified according to tumor risk category. The trial did not evaluate effects on progression or mortality. Patients were randomized to intravesical HAL or placebo administered one hour prior to white light cystoscopy, which was performed in all patients. Surgeons were blinded to treatment allocation until after white light cystoscopy was completed; only patients randomized to HAL underwent fluorescent cystoscopy.

We updated the meta-analyses on recurrence with data from the new trial. We also found errors in the data used for long-term recurrence and progression for one trial<sup>8</sup> included in the original report and used corrected data in the updated meta-analysis. The updated analyses resulted in similar estimates and conclusions and are shown in Table 3. Estimates and overall conclusions were similar to those in the original report.

**Table 3. Updated results for fluorescent cystoscopy versus white light cystoscopy**

Outcome	Number of trials	Relative risk, fluorescent cystoscopy versus white light cystoscopy (95% confidence interval)*	I <sup>2</sup>
Short-term (<3 months) recurrence	9	0.59 (0.40 to 0.88)	69%
HAL	6	0.62 (0.38 to 1.00)	51%
5-ALA	4	0.57 (0.28 to 1.16)	84%
Intermediate-term (3 months to <1 year) recurrence	6	0.70 (0.56 to 0.88)	19%
Long-term ( $\geq 1$ year) recurrence	12	0.81 (0.70 to 0.93)	49%
HAL	7	0.75 (0.62 to 0.92)	41%
5-ALA	5	0.86 (0.68 to 1.08)	65%
Progression	9	0.74 (0.52 to 1.03)	0%
HAL	4	0.51 (0.28 to 0.96)	0%
5-ALA	5	0.86 (0.57 to 1.28)	0%
Mortality	3	1.28 (0.55 to 2.95)	43%

HAL=hexaminolevulinate, 5-ALA=aminolevulinic acid

\*p for interaction based on photosensitizer used 0.97 for short-term recurrence, 0.41 for long-term recurrence, and 0.18 for progression

Study characteristics and risk of bias ratings for the additional studies are shown in Tables 4, 5 and 6.

**Table 4. Characteristics and results of additional trials of intravesical therapy**

Author, Year Risk of Bias	Inclusion Criteria	Population Characteristics	Intervention	Followup Duration	Main Results
Barghi, 2006 <sup>1</sup> Medium	Primary or papillary tumors, single tumors of 3 cm or less in size, and low-grade superficial tumors (TaG1, TaG2, T1G1)	Age, mean (years): 56 vs. 54 Male: 77% vs. 81% Recurrent bladder cancer: NR Ta: 73% vs. 71% T1: 28% vs. 29% G1: 91% vs. 91% G2: 9% vs. 9%	A: Mitomycin C 30 mg (in 30mL distilled water). Single instillation 6 to 24 hours after TURBT. Catheter clamped for 2 hours (n=22).  B: Placebo (distilled water). Single instillation 6 to 24 hours after TURBT. Catheter clamped for 2 hours (n=21).	24 months	Recurrence within 1 year: 4.5% (1/22) vs. 38.1% (8/21), p=0.007  Progression within 1 year: 0% (1/22) vs. 14.3% (3/21), p=0.06
El-Ghobashy, 2007 <sup>2</sup> High	2 cm or less, single, papillary, primary or recurrent transitional cell carcinoma of the urinary bladder, who were disease free for more than 1 year.	Age, mean (years): 62.2 vs. 59.9 Sex: NR Recurrent bladder cancer: 9.7% vs. 13% Ta: 18% vs. 50% T1: 52% vs. 50% G1: 48% vs. 53% G2: 52% vs. 47%	A: Mitomycin, 30mg (in 50mL saline), instilled when hematuria stopped, usually within 6 hours of TURBT. Catheter clamped for 1 hour (n=31).  B: No adjuvant treatment. TURBT alone (n=32).	Mean (months): 44 vs. 43	Recurrence within two years: 16.1% (5/31) vs. 34.3% (11/32), p<0.05  Recurrence after 2 years: 26.9% (7/31) vs. 28.6% (6/32), non significant  Progression: 3.2% (1/31) vs. 3.1% (1/32), non significant

Solsona, 2015 <sup>4</sup> Medium	Papillary NMIBC, TaG3 or T1G1-3 tumors, and Tis alone or associated with papillary tumors Ta-1G1-3	Age: 65 vs. 66 years Male: 91% vs. 89% Recurrent bladder cancer: 29% vs. 35% Stage Ta: 17% vs. 16% Stage T1: 77% vs. 74% Grade G1: 16% vs. 10% Grade G2: 64% vs. 59% Grade G3: 20% vs. 31%	A: MMC, 30 mg (in 50 mL water), later reduced to 10 mg due to adverse effects one day prior to BCG Connaught, 1.5-5 x 108 CFU (in 50 mL water). Total 9 instillations; 6 weekly instillations starting 14 to 28 days after TURBT, then 3 instillations every 2 weeks (n=211).  B: BCG Connaught, 1.5-5 x 108 CFU (in 50 mL water). Total 9 instillations; 6 weekly instillations starting 14 to 28 days after TURBT, then 3 instillations every 2 weeks (n=196).	Median (years): 7.1 years	Bladder cancer mortality: 4.7% (10/211) vs. 7.6% (15/196), RR 0.62 (95% CI 0.28 to 1.35)  All-cause mortality: 24% (51/211) vs. 26% (52/196), RR 0.91 (95% CI 0.65 to 1.27)  Recurrence (Ta, T1, or Tis tumor): 18% (38/211) vs. 33% (64/196), RR 0.55 (95% CI 0.39 to 0.78)  Relapse (Ta, T1, Tis, or upper urinary tract tumor, prostatic urethral involvement, T2 or higher tumor, nodal involvement or metastasis): 21% (44/211) vs. 35% (68/196), RR 0.60 (95% CI 0.43 to 0.83)
Yokomizo, 2015 <sup>6</sup> Medium	CIS or unresectable NMIBC with CIS, age 20-85	Age: 68 vs. 68 (CIS, n=155), 67 vs. 72 (no CIS, n=21) Male: 80% vs. 85% (CIS), 91% vs. 70% (no CIS) Race/ethnicity: Not reported Recurrent bladder cancer: 13% vs. 13% (CIS), 14% vs. 20% (no CIS) Stage Tis, pure (CIS): 49% vs. 36%, Stage Ta + Tis (CIS): 26% vs. 33% Stage T1 + Tis (CIS): 26% vs. 19% Stage Ta (no CIS): 55% vs. 70% Stage T1 (no CIS): 45% vs. 30%	A: BCG Tokyo strain, 40 mg once weekly for 8 weeks (n=81)  B: BCG Tokyo strain, 80 mg once weekly for 8 weeks (n=85)	Median 3.6 years	Complete response (no residual tumor): 78% vs. 85% (p=0.12) Recurrence-free survival: p=0.94 Progression: 5/81 vs. 5/86

# Appendix B. PICOTS

**Table B1. PICOTS**

PICOT	Inclusion and Exclusion Criteria
Populations	<p>Include:</p> <p>Patients with signs or symptoms of possible bladder cancer [KQ 1; KQ 6; KQ7]</p> <p>Patients with non-muscle invasive bladder cancer (stages Ta, Tis, or T1) [KQ 2]</p> <p>Adults with non-muscle invasive bladder cancer treated with TURBT [KQ 3; KQ 8]</p> <p>Adults with high-risk non-muscle invasive bladder cancer treated with TURBT [KQ4; KQ8]</p> <p>Adults undergoing surveillance following treatment for non-muscle invasive bladder cancer [KQ 1; KQ 5; KQ 6; KQ 7]</p>
Interventions	<p>Include:</p> <p>Urinary biomarkers [KQ 1; KQ 5; KQ 7]</p> <p>Risk-adapted treatment approaches [KQ 2]</p> <p>Intravesical chemotherapeutic or immunotherapeutic agents [KQ 3; KQ 8]</p> <p>External beam radiation therapy, with or without systemic chemotherapy or immunotherapy [KQ 4]</p> <p>Blue light cystoscopy or other methods of augmented cystoscopy</p> <p>Biomarkers included are: BTastat<sup>®</sup> [BTA], Alere NMP22<sup>®</sup>, BladderChek<sup>®</sup> [NMP22], UroVysion<sup>®</sup> [FISH] and ImmunoCyt<sup>™</sup> [immunocytology], CxBladder<sup>™</sup></p> <p>Chemotherapeutic and immunotherapeutic agents of interest include: mitomycin; apaziquone; paclitaxel; gemcitabine; thiotepa; valrubicin; doxorubicin; epirubicin; bacillus Calmette-Guérin (BCG); and interferon</p> <p>Exclude:</p> <p>Electromotive drug administration</p>
Comparators	<p>Include:</p> <p>Other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology and imaging) [KQ 1; KQ 5; KQ 7]</p> <p>Treatment not guided by risk-adapted approach [KQ 2]</p> <p>Other Intravesical chemotherapeutic or immunotherapeutic agent, different dose or duration of intravesical chemotherapy or immunotherapy, or TURBT alone [KQ 3; KQ 8]</p> <p>Intravesical chemotherapeutic or immunotherapeutic agents or cystectomy. [KQ 4]</p>
Outcomes	<p>Include:</p> <p>Diagnostic accuracy, using cystoscopy with biopsy as the reference standard [KQ 1; KQ 5]</p> <p>Mortality, disease specific and all-cause [KQ 2; KQ 3; KQ 4; KQ 5]</p> <p>Need for cystectomy [KQ 2; KQ 3; KQ 4; KQ 5]</p> <p>Recurrence of cancer [KQ 2; KQ 3; KQ 4; KQ 5; KQ 6]</p> <p>Progression of cancer [KQ 2; KQ 3; KQ 4; KQ 5]</p> <p>Quality of life [KQ 2; KQ 3; KQ 4; KQ 5]</p> <p>Adverse effects of diagnostic testing [KQ 7]</p> <p>Adverse effects of treatment [KQ 8]</p> <p>Exclude:</p> <p>Prediction of treatment response</p>
Timing	<p>Include:</p> <p>Any duration of followup</p>
Setting	<p>Include:</p> <p>Inpatient or outpatient settings</p>
Study Design	<p>Include:</p> <p>RCTs, Cohort Studies Must be comparative</p> <p>Systematic reviews must evaluate quality of individual studies</p>

KQ = key question; PICOTS = populations, interventions, comparators, outcomes, timing, setting; RCT = randomized controlled trial; T1 = Tumor stage 1; Ta = Tumor stage a; Tis = carcinoma in situ; TURBT = transurethral resection of bladder tumor

## Appendix C. Included Studies

**Please refer to this section as a reference list for Appendixes E and F.**

Abrams PH, Choa RG, Gaches CG, et al. A controlled trial of single dose intravesical adriamycin in superficial bladder tumours. *Br J Urol.* 1981;53(6):585-7. PMID: 7032640.

Addeo R, Caraglia M, Bellini S, et al. Randomized phase III trial on gemcitabine versus mitomycin in recurrent superficial bladder cancer: evaluation of efficacy and tolerance. *J Clin Oncol.* 2010;28(4):543-8. PMID: 19841330.

Akaza H, Isaka S, Koiso K, et al. Comparative analysis of short-term and long-term prophylactic intravesical chemotherapy of superficial bladder cancer. Prospective, randomized, controlled studies of the Japanese Urological Cancer Research Group. *Cancer Chemother Pharmacol.* 1987;20 Suppl:S91-6. PMID: 3117403.

Akaza H, Koiso K, Kotake T, et al. Long-term results of intravesical chemoprophylaxis of superficial bladder cancer: experience of the Japanese Urological Cancer Research Group for Adriamycin. *Cancer Chemother Pharmacol.* 1992;30 Suppl:S15-20. PMID: 1394810.

Ali-el-Dein B, el-Baz M, Aly AN, et al. Intravesical epirubicin versus doxorubicin for superficial bladder tumors (stages pTa and pT1): a randomized prospective study. *J Urol.* 1997;158(1):68-73; discussion -4. PMID: 9186325.

Ali-el-Dein B, Nabeeh A, el-Baz M, et al. Single-dose versus multiple instillations of epirubicin as prophylaxis for recurrence after transurethral resection of pTa and pT1 transitional-cell bladder tumours: a prospective, randomized controlled study. *Br J Urol.* 1997;79(5):731-5. PMID: 9158511.

Ali-El-Dein B, Nabeeh A, Ismail EH, et al. Sequential bacillus Calmette-Guerin and epirubicin versus bacillus Calmette-Guerin alone for superficial bladder tumors: a randomized prospective study. *J Urol.* 1999;162(2):339-42. PMID: 10411034.

Au JL, Badalament RA, Wientjes MG, et al. Methods to improve efficacy of intravesical mitomycin C: results of a randomized phase III trial. *J Natl Cancer Inst.* 2001;93(8):597-604. PMID: 11309436.

Babjuk M, Soukup V, Petrik R, et al. 5-aminolaevulinic acid-induced fluorescence cystoscopy during transurethral resection reduces the risk of recurrence in stage Ta/T1 bladder cancer. *BJU Int.* 2005;96(6):798-802. PMID: 16153204.

Badalament RA, Herr HW, Wong GY, et al. A prospective randomized trial of maintenance versus nonmaintenance intravesical bacillus Calmette-Guerin therapy of superficial bladder cancer. *J Clin Oncol.* 1987;5(3):441-9. PMID: 3546618.

Bassi P. Dose Response of Bacillus Calmette-Guerin (BCG) in superficial bladder cancer: a phase III randomized trial low-dose vs standard-dose BCG regimen. *J Urol.* 1992;146:32-5.

## Appendix E. Data Abstraction of Included Studies

**Table E1. Key Question 1: Diagnostic accuracy**

<b>Author, Year Country Risk of Bias</b>	<b>Screening Test</b>	<b>Method of Data Collection</b>	<b>Reference Standard</b>	<b>Inclusion Criteria</b>	<b>Subjects</b>
Cha, 2012 Germany Medium	ImmunoCyt	Prospective	Cystoscopy with pathological confirmation and imaging	Patients with painless hematuria (microscopic or gross) and no prior bladder cancer	Median age: 65 years Male: 78% Race: NR Smoker: NR Signs or symptoms: 68% microscopic hematuria and 32% gross hematuria Prior bladder cancer stage/grade: None with prior bladder cancer
Chahal, 2001 United Kingdom Medium	NMP22 (quantitative)	Prospective	Cystoscopy with pathological Confirmation	Patients with hematuria or irritative symptoms (n=96) or undergoing surveillance for treated bladder cancer (n=115)	Age: NR Sex: NR Race: NR Smoker: NR Signs or symptoms: NR Prior bladder cancer stage/grade: NR
Feil, 2003 Germany Medium	ImmunoCyt	Unclear	Cystoscopy with pathological Confirmation	Patients suspected of having TCC (n=41), symptoms suggestive of tumor recurrence (n=46), or undergoing surveillance (n=34)	Mean age: 62 years Male: 82% Race: NR Smoker: NR Signs or symptoms: NR Prior bladder cancer stage/grade: NR

<b>Author, Year Country Risk of Bias</b>	<b>Proportion With Bladder Cancer, Bladder Cancer Stage and Grade</b>	<b>Definition of a Positive Screening Exam</b>	<b>Proportion Unexamined by Screening Test</b>	<b>Proportion Who Did Not Undergo Reference Standard and Excluded From Analysis</b>
Cha, 2012 Germany Medium	202/1182 (21%) Tumor stage: 160 Ta, 44 T1, 26 T2-T4 Tumor grade: 138 low grade, 97 high grade	ImmunoCyt: Positive ( $\geq 1$ fluorescent cell)	23 with inconclusive ImmunoCyt results (excluded)	None reported
Chahal, 2001 United Kingdom Medium	16/96 (17%) primary Tumor stage: 7 Ta, 5 T1, 3 T2, 1 T1 Tumor grade: 6 G1, 3 G2, 7 G3  17/115 (16%) recurrent Tumor stage: 15 Ta, 2 T1 Tumor grade: 13 G1, 3 G2, 1 G3	NMP22 (quantitative): $>10$ U/mL (also $>3.75$ , $>6.4$ , $>10$ , $>15.25$ )	NR	None reported
Feil, 2003 Germany Medium	26/113 (23%) Tumor stage: 11 Ta, 8 T1, 7 T2 Tumor grade: 7 G1, 19 G2/G3	ImmunoCyt: Positive ( $\geq 1$ fluorescent cell)	8 specimens "could not be evaluated"	None reported

Author, Year Country Risk of Bias	Sensitivity- Report as n/N	Specificity-Report as n/N	Positive Likelihood Ratio	Negative Likelihood Ratio
Cha, 2012 Germany Medium	0.82 (202/245)	0.87 (811/937)	6.3	0.21

<b>Author, Year Study Design Risk of Bias</b>	<b>Setting (country, single/multi-sites) Study Years</b>	<b>Inclusion Criteria</b>	<b>Exclusion Criteria</b>	<b>Type of Intervention (experimental and control groups, dose, duration of treatment)</b>	<b>Duration of Followup and Followup Method</b>
Abrams, 1981 RCT High	United Kingdom Single Center Study years: NR	Histologically confirmed superficial bladder tumor. Recurrent only, with presence of tumors at both of two previous endoscopies 12 months and 6 months before entry into trial. Stages Ta or T1; Included grades not specified, but "well" and "moderate" differentiation included.	None explicitly stated.	A: Doxorubicin, 50 mg (in 50 mL saline). Single installation, within 24 hours of TURBT.  B: No adjuvant treatment. TURBT alone.	Duration: 6 months for all patients. Method: Cystoscopy

Author, Year Study Design Risk of Bias	Number of Treatment and Control Subjects (screened, randomized, postrandomization exclusions, lost to followup, total and per group analyzed)	Population Characteristics by Treatment Group (age, race, sex, smoking status, recurrent bladder cancer, stage of disease, functional status)	Results: Primarily recurrence, progression, survival
Abrams, 1981 RCT High	Screened: NR Randomized: 60 Postrandomization exclusions: 2 Lost to followup: 1 Total Analyzed: 57 Per Group Analyzed (A vs. B): 29 vs. 28	A vs. B All characteristics reported for 60 randomized patients (30 per group), not the groups analyzed: Age (mean), years: 72 vs. 68 Male: 70% vs. 79% Race: NR Smoking status: NR Recurrent bladder cancer: 100% vs. 100% Stage: Ta: 73.3% vs. 76.7%; T1: 26.7% vs. 23.3%; Grade: Well Differentiated: 70.0% vs. 63.3%; Moderately Differentiated: 30.0% vs. 36.7% Functional Status: NR	Recurrence at 6 months: 79.3% (23/29) vs. 89.3% (25/28)

<b>Author, Year Study Design Risk of Bias</b>	<b>Results: According to Tumor Characteristics</b>	<b>Results: According to Patient Characteristics</b>	<b>Adverse Events and Withdrawals due to Adverse Events</b>	<b>Sponsor</b>	<b>Comments</b>
Abrams, 1981 RCT High	No data reported. "The response to Adriamycin did not appear to be related to any recognised pre-treatment factors, such as number of bladder tumours, stage of tumour (pTa or pT1), or to the histological differentiation of the tumours."	NR	Group A (NR for group B): Severe bladder pain: n=1 Bladder discomfort for up to 24 hours after instillation: n=6 No change in "full blood count".	NR	

<b>Author, Year Study Design Risk of Bias</b>	<b>Setting (country, single/multi-sites) Study Years</b>	<b>Inclusion Criteria</b>	<b>Exclusion Criteria</b>	<b>Type of Intervention (experimental and control groups, dose, duration of treatment)</b>	<b>Duration of Followup and Followup Method</b>
Akaza, 1987 RCTs (2 studies) Study One (followup of Niiijima, 1983) Medium	Japan Multicenter Study years: April 1980 - 1985	Histologically proven superficial bladder cancer (primary or recurrent). Stages Ta or T1; Grade not specified. Absence of tumor after TURBT.	Tis superficial cancer; other therapies, such as chemotherapy, immunotherapy, and/or radiotherapy within 3 or 4 weeks before initiation of study; severe cardiovascular, renal, hepatic or hematopoietic disturbances; simultaneous presence of another cancer.	A: Doxorubicin, 30 mg (in 30 mL saline).  B: Doxorubicin, 20 mg (in 40 mL saline).  C: Mitomycin C: 20 mg (in 40 mL saline).  D: No adjuvant treatment. TURBT alone.  For A, B, and C: First instillation within 1 week of TURBT. Twice weekly X 4 weeks (Total: 8 doses)	Duration: 5 years, maximum; NR as median/mean, nor for each group.  Method: Cystoscopy and urinary cytology studies at 12-week intervals during the observation period.

Author, Year Study Design Risk of Bias	Number of Treatment and Control Subjects (screened, randomized, postrandomization exclusions, lost to followup, total and per group analyzed)	Population Characteristics by Treatment Group (age, race, sex, smoking status, recurrent bladder cancer, stage of disease, functional status)	Results: Primarily recurrence, progression, survival

Berrum-Svennung, 2008 RCT Medium	Sweden Multicenter September 1998 - September 2004	Non-muscle invasive papillary bladder tumor (primary or recurrent). Stage Ta or T1; Grade G1 or G2. Maximal tumor diameter 30 mm.	Intravesical treatment with BCG or chemotherapy in previous year; History of muscle-invasive tumor or grade G3 tumor; Stage T2.	A: Epirubicin, 50 mg (in 50 mL saline). Single instillation within 6 hours after TURBT. Catheter clamped X 1 hour.  B: Placebo. Saline, 50 mL. Single instillation within 6 hours after TURBT. Catheter clamped X 1 hour.	Duration: 2 years  Method: Evaluated with cystoscopy according to the routine at each study center. Study plan recommended cystoscopy every 4 months X 1 year, then every 6 months X 1 year. Participants were free to follow their respective clinical routines after instillation.

Gudjónsson, 2009 RCT Medium	Sweden Multicenter Study years: 1997 - 2004	Low to intermediate risk bladder tumors (primary or recurrent). Stages Ta or T1; Grade G1 or G2. Single or multiple tumors. No upper limit on size.	CIS; Grade 3 cancer; Muscle-invasive tumor. History of high-risk tumor (G3 or CIS) and intravesical therapy within previous year; upper urinary tract tumor; age > 85 years. Patients with muscle invasion on re-TURBT. Histopathology report could not confirm malignancy.	A: Epirubicin, 80 mg (in 30 mL saline) intravesically as soon as possible within 24 hours of TURBT. A single instillation, retained intravesically for 1 hour; fluid restriction and patient position changed every 15 minutes.  B: No adjuvant treatment. TURBT alone.	Duration: median 3.9 years. Median (patients without recurrence): 3.6 years (range: 0.4 - 7.4 years)  Method: Cystoscopy and urine cytology, every 3 months during year 1, and every 4 months during year 2. Thereafter, surveillance performed according to local routines at each center.

Kurth, 1997 RCT (followup of Kurth, 1984) Medium	Europe (multinational) Multicenter Study years: December 1979 - December 1983	Histologically proved, transurethrally resectable transitional cell carcinoma of the bladder or carcinoma in situ (primary or recurrent). Stages Ta or T1; Grade G0, G1, G2 or G3.	None reported	A: Doxorubicin, 50 mg (in 50 mL normal saline). First instillation 3 to 14 days after TURBT and retained for 1 hour. Then, weekly for 1 month, then monthly for 11 months. Nitrofurantoin, 100 mg, was given after each instillation 3 times/day X 3 days. WBC, platelets, and urinalysis before each instillation. Chemotherapy delayed until WBC $\geq 4 \times 10^9/L$ and platelets $\geq 1.5 \times 10^9/L$ ; or until any bacterial cystitis was controlled.  B: No adjuvant treatment. TURBT alone.	Duration, median: For recurrence: 3.4 years For Invasion: 5 years For Time to death from malignancy: 7.2 years For Survival: 10.7 (maximum followup 14 years).  Method: Cystoscopy every 12 weeks during year 1, every 16 weeks during year 2, and every 24 weeks thereafter.

Author, Year Study Design Risk of Bias	Setting (country, single/multi-sites) Study Years	Inclusion Criteria	Exclusion Criteria	Type of Intervention (experimental and control groups, dose, duration of treatment)
Ali-El-Dein, 1997 (J Urol) RCT Medium	Egypt Single center Study years: June 1991 - May 1995	Transitional cell carcinoma (TCC) of the bladder (primary or recurrent). Stages Ta or T1; Associated CIS or other dysplastic mucosal changes; Grade G1 - G3. Rapid recurrence within 6 months of initial resection; Multicentricity; Positive posterior urethral biopsy and/or positive postoperative urinary cytology (only 2 patients with positive posterior urethral biopsy, who underwent resection of multiple tumors to provide bladder neck incompetence and sufficient contact of drug with prostatic urethra).	Prior pelvic radiotherapy or chemotherapy; Abnormal cardiac, hematologic, renal, or bladder function.	A: Epirubicin, 50 mg (in 50 mL normal saline). B: Epirubicin, 80 mg (in 50 mL normal saline). C: Doxorubicin, 50 mg (in 50 mL normal saline). D: No adjuvant treatment. TURBT alone.  For Groups A - C: First instillation 7 to 14 days after TURBT. Retained intravesically for 2 hours; instillations once a week X 8 weeks, then once monthly to complete 1 year of treatment.

Author, Year Study Design Risk of Bias	Setting (country, single/multi-sites) Study Years	Inclusion Criteria	Exclusion Criteria	Type of Intervention (experimental and control groups, dose, duration of treatment)
Ali-El-Dein, 1999 RCT Medium	Egypt Single center 1993-1997	Grade 2 or 3, stage pT1 disease, rapid disease recurrence within 6 months of initial resection, multicentricity, aneuploid DNA pattern, tumor size equal to or not more than 3 cm, assoc carcinoma in situ or other dysplastic mucosal changes and/or positive postoperative urinary cytology	Prior pelvic radiotherapy or systemic chemotherapy	1-3 weeks after transurethral resection of bladder tumor:  A. BCG/epirubicin: alternating weekly 150 mg Pasteur strain 5x10 <sup>8</sup> to 5x10 <sup>6</sup> CFU BCG with 50 mg epirubicin in 50 mL saline for 2 hours  B. BCG only: 150 mg in 50 mL saline for 2 hours  Treatment was weekly for 6 weeks then monthly for 10 months
Bilen, 2000 RCT Medium	Turkey Single center 1994-1995	Superficial transitional-cell carcinoma of the bladder; patients with pT1 who had an additional one of four prognostic factors (grade 3 tumors, multiple tumors, tumors greater than 40 mm, recurrent tumors) were included	Patients with Ta tumors, previous treatment with any kind of intravesical therapy, radiotherapy, systemic chemotherapy were excluded	A. BCG 81 mg (Connaught strain) weekly for 6 weeks  B. Sequential BCG 81 mg (Connaught) and epirubicin 50 mg with epirubicin given weeks 1, 2, 3, 4, and 12 and BCG given weeks 5, 6, 7, 9, 10, and 11
Boccardo, 1994 RCT Medium	Italy Number sites: unclear (authors from 5 centers) Study years (enrollment): March 1987 - December 1989	Primary superficial bladder cancer (no prior history of bladder tumors). Stages and Grade: pTa G2; pT1 G1; pT1 G2. Negative urine cytology after TURBT; No previous local or systemic treatment for the disease; No evidence of concurrent conditions that might alter compliance with protocol; geographic ineligibility.	Primary or secondary CIS; Tumors involving prostatic urethra; urethral stenosis; active urinary infection.	A: Mitomycin (MMC), 40 mg (in 50 mL saline) intravesical, with retention "suggested" for 120 minutes; weekly dose X 8 weeks. Drug retained in bladder for approx. 120 minutes: yes, 124 (87.9%); no, 10 (7.1%); unknown, 7 (5.0%).  B: Interferon alfa-2b (IFN), 50 X 10 <sup>6</sup> IU (in 50 mL saline) intravesical, with retention "suggested" for 120 minutes; weekly dose X 8 weeks. Drug retained in bladder for approx. 120 minutes: yes, 135 (92.4%); no, 8 (5.5%); unknown, 3 (2.1%).

<b>Author, Year Study Design Risk of Bias</b>	<b>Setting (country, single/multi-sites) Study Years</b>	<b>Inclusion Criteria</b>	<b>Exclusion Criteria</b>	<b>Type of Intervention (experimental and control groups, dose, duration of treatment)</b>
Witjes, 1998 RCT Medium	The Netherlands Multicenter 1991-1993	Histologically proved primary multiple (more than 2 tumors) or recurrent multiple (2 or more tumors) stage pTa or pT1 transitional cell carcinoma, solitary or multiple grade III tumors and primary or concomitant CIS	Previous radiotherapy, intravesical or systemic chemotherapy within 3 months of the study	A. MMC 40 mg in 50 mL saline weekly for 4 weeks followed by BCG (Tice strain) $5 \times 10^8$ in 50 mL saline weekly for 6 weeks  B. MMC 40 mg in 50 mL saline weekly for 10 weeks
Zincke, 1985 RCT Medium	USA Single center Study years NR	Transitional cell cancer, any grade, Ta or Tis	Previous systemic or intravesical treatment with chemotherapy, previous pelvic radiotherapy, limited bladder capacity, urinary incontinence, second malignancy	A. MMC 40 mg in 40 mL distilled water  B. Thiotepa 60 mg in 60 mL distilled water  Biweekly treatment for a total of 5 treatments. If no tumor was present at the first 3-month assessment the treatment interval was lengthened to every 4 weeks for 6 months. If there still was no recurrence, there was no further treatment. If tumor recurred during the primary treatment, patients were given the opposite drug.

Author, Year Study Design Risk of Bias	Duration of Followup and Followup Method	Number of Treatment and Control Subjects (screened, randomized, postrandomization exclusions, lost to followup, total and per group analyzed)	Population Characteristics by Treatment Group (age, race, sex, smoking status, recurrent bladder cancer, stage of disease, functional status)
Witjes, 1998 RCT Medium	Duration: Median 32 months (range 2-65 months)  Method: cystoscopy and cytology every 3 months until recurrence	Screened: NR Randomized: 182 (90 vs. 92) Post-randomization exclusions: None reported Loss to followup: None reported Analyzed: 182 (90 vs. 92)	Age: NR Male: NR Race: NR Smoking: NR Stage: pTa: 43 (48%) vs. 36 (39%) pT1: 36 (40%) vs. 47 (51%) Grade: Grade 1: 19 (21%) vs. 16 (17%) Grade 2: 42 (47%) vs. 44 (48%) Grade 3: 18 (20%) vs. 24 (26%) CIS: 29 (32%) vs. 36 (39%)

<b>Author, Year Study Design Risk of Bias</b>	<b>Setting (country, single/multi-sites) Study Years</b>	<b>Inclusion Criteria</b>	<b>Exclusion Criteria</b>	<b>Type of Intervention (experimental and control groups, dose, duration of treatment)</b>
Akaza, 1987 RCT (Also Akaza 1992) Study Two Medium	Japan Number sites: Unclear Study years: July 1982 1985	Histologically proven superficial bladder cancer (primary only). Stages Ta or T1; Grade G1 or G2. Absence of tumor after TURBT.	Tis superficial cancer; other therapies, such as chemotherapy, immunotherapy, and/or radiotherapy within 3 or 4 weeks before initiation of study; severe cardiovascular, renal, hepatic or hematopoietic disturbances; simultaneous presence of another cancer.	A: Doxorubicin, 30 mg (in 30 mL saline). B: Doxorubicin, 20 mg (in 40 mL saline). C: Mitomycin C: 20 mg (in 40 mL saline). D: No adjuvant treatment. TURBT alone.  For A, B, and C: First instillation within 1 week of TURBT. Once weekly X 2 weeks then once every 2 weeks X 14 week, then once monthly X 8 months, then once every 3 month X 1 year (Total: 21 doses over 2 years)
Ali-El-Dein, 1997 (British J Urol) RCT Medium	Egypt Single Center Study years: January 1992 - February 1996	Transitional cell carcinoma (TCC) of the bladder (primary or recurrent). G2 or G3, multiple recurrent, pT1, aneuploidy, or $\geq 3$ cm; pTa if multiple, large ( $\geq 3$ cm), recurrent and/or grade 2-3 tumors.	Prior pelvic radiotherapy or chemotherapy; Abnormal cardiac, hematologic, renal, or bladder function; CIS.	A: Epirubicin, 50 mg (in 50 mL normal saline); Single instillation immediately after TURBT. Retained intravesically for 2 hours.  B: Epirubicin, 50 mg (in 50 mL normal saline); Initial instillation 1 - 2 weeks after TURBT. Retained intravesically for 2 hours; Then, instillations once a week X 7, then once monthly X 10 to complete 1 year of treatment.  C: No adjuvant treatment. TURBT alone.

Please see Appendix C. Included Studies for full study references.

**Table F3. Assessment of risk of bias of cohort studies**

Author, Year	Did the study attempt to enroll all (or a random sample of) patients meeting inclusion criteria, or a random sample (inception cohort)?	Were the groups comparable at baseline on key prognostic factors (age, sex, race, smoking status-if available, bladder cancer stage; e.g., by restriction or matching)?	Did the study maintain comparable groups through the study period?	Did the study use accurate methods for ascertaining exposures and potential confounders?	Were outcome assessors and/or data analysts blinded to the exposure being studied?	Did the article report attrition?	Did the study perform appropriate statistical analyses on potential confounders?	Overall loss to followup <20%? Differential attrition <10%?	Were outcomes prespecified and defined, and ascertained using accurate methods?	Risk of Bias
Mulders, 1994	Yes, all patients in registry	Yes	Yes	No	Not reported	Yes	No	No	Yes	High

**Please see Appendix C. Included Studies for full study references.**

## Appendix G. Strength of Evidence

Table G1. Strength of evidence

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
<b>1. What is the diagnostic accuracy of various urinary biomarkers compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging) in 1) persons with signs or symptoms warranting evaluation for possible bladder cancer or 2) persons undergoing surveillance for previously treated bladder cancer?</b>							
<b>Quantitative NMP22:</b> Sensitivity and specificity	19 studies of diagnostic accuracy	Moderate	Inconsistent	Direct	Precise	Not detected	Moderate
<b>Qualitative NMP22:</b> Sensitivity and specificity	4 studies of diagnostic accuracy	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
<b>Qualitative BTA:</b> Sensitivity and specificity	22 studies of diagnostic accuracy	Moderate	Inconsistent	Direct	Precise	Not detected	Moderate
<b>Quantitative BTA:</b> Sensitivity and specificity	4 studies of diagnostic accuracy	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
<b>FISH:</b> Sensitivity and specificity	11 studies of diagnostic accuracy	Moderate	Inconsistent	Direct	Imprecise	Not detected	Moderate
<b>ImmunoCyt:</b> Sensitivity and specificity	14 studies of diagnostic accuracy	Moderate	Inconsistent	Direct	Imprecise	Not detected	Moderate
<b>CxBladder:</b> Sensitivity and specificity	1 study of diagnostic accuracy	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Quantitative NMP22 versus qualitative BTA: Sensitivity and specificity	7 studies of diagnostic accuracy	Moderate	Consistent	Direct	Precise	Not detected	Moderate
ImmunoCyt versus FISH: Sensitivity and specificity	3 studies	Moderate	Consistent	Direct	Precise	Not detected	Low
Other head-to-head urinary biomarkers							Insufficient
Various urinary biomarkers plus cytology versus the urinary biomarker alone: Sensitivity and specificity	16 studies of diagnostic accuracy	Moderate	Consistent	Direct	Precise	Not detected	Moderate
<b>KQ1a. Does the diagnostic accuracy differ according to patient characteristics (e.g., age, sex, ethnicity), or according to the nature of the presenting signs or symptoms?</b>							

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
Effects of tumor stage: Sensitivity	Quantitative NMP22: 11 studies Qualitative BTA: 18 studies FISH: 8 studies ImmunoCyt: 10 studies	Moderate	Consistent	Direct	Precise	Not detected	High
Effects of tumor grade: Sensitivity	Quantitative NMP22: 12 studies Qualitative BTA: 18 studies ImmunoCyt: 10 studies FISH: 9 studies	Moderate	Consistent	Direct	Precise	Not detected	High
Effects of tumor size: Sensitivity	2 studies	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Effects of patient characteristics (age, sex, smoking status, and presence of other clinical conditions): sensitivity and specificity		Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>2. For patients with non-muscle-invasive bladder cancer, does the use of a formal risk-adapted assessment approach to treatment decisions (e.g., Guidelines of the European Association of Urology or based on urinary biomarker tests) decrease mortality or improve other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with treatment not guided by an assessed risk-adapted approach?</b>							
Mortality, recurrence, progression, need for cystectomy, quality of life	No studies	-	-	-	-	-	Insufficient

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
<b>3. For patients with non-muscle-invasive bladder cancer treated with transurethral resection of bladder tumor (TURBT), what is the effectiveness of various intravesical chemotherapeutic or immunotherapeutic agents for decreasing mortality or improving other outcomes (e.g., recurrence, progression, need for cystectomy, quality of life) compared with other agents, TURBT alone, or cystectomy?</b>							
<b>BCG vs. no intravesical therapy</b>							
All-cause mortality	No studies	-	-	-	-	-	Insufficient
Bladder cancer-specific mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Insufficient
Recurrence	3 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Low
Progression	4 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Low
<b>MMC vs. no intravesical therapy</b>							
All-cause mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Bladder cancer-specific mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Recurrence	8 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
Progression	5 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>Doxorubicin vs. no intravesical therapy</b>							
All cause mortality	2 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
Bladder cancer-specific mortality	1 RCTs	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Recurrence	10 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
Progression	5 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>Epirubicin vs. no intravesical therapy</b>							
Recurrence	9 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
Progression	8 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Low
<b>Gemcitabine vs. no intravesical therapy</b>							
All-cause mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Insufficient
Bladder cancer-specific mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Insufficient
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Insufficient
<b>Interferon-alpha vs. no intravesical therapy</b>							
Bladder cancer-specific mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Recurrence	3 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Progression	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>Interferon-gamma vs. no intravesical therapy</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>Thiotepa vs. no intravesical therapy</b>							
Recurrence	4 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>3a. What is the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents, as monotherapy or in combination?</b>							
<b>BCG versus MMC</b>							
All-cause mortality	7 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
Bladder cancer- specific mortality	5 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
Recurrence	9 RCTs	Moderate	Inconsistent	Direct	Precise	Not detected	Low
Progression	7 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
<b>BCG vs. BCG plus MMC given sequentially</b>							
All-cause mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Bladder cancer- specific mortality	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Recurrence	4 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
Progression	3 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>BCG plus MMC given sequentially vs. MMC</b>							
All-cause mortality	2 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
Bladder cancer- specific mortality	2 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
Recurrence	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Progression	2 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
<b>BCG vs. doxorubicin</b>							
All-cause mortality	2 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
Recurrence	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. epirubicin</b>							
All-cause mortality	3 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
Bladder cancer-specific mortality	3 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
Recurrence	5 RCTs	Moderate	Inconsistent	Direct	Precise	Not detected	Moderate
Progression	5 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>BCG vs. BCG plus epirubicin given sequentially</b>							
Recurrence	3 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Progression	3 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>BCG vs. Epirubicin plus interferon</b>							
Bladder cancer-specific mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. gemcitabine</b>							
All-cause mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
Recurrence	3 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Insufficient
Progression	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Quality of life	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. BCG plus gemcitabine given sequentially</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. interferon alpha-2a</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. alternating BCG and interferon alpha-2b</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. coadministration of BCG and interferon alpha-2b</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. thiotepa</b>							
Recurrence	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>MMC vs. doxorubicin</b>							
Recurrence	6 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Progression	4 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
<b>MMC vs. epirubicin</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC vs. gemcitabine</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC vs. interferon-alpha</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC vs. interferon-gamma</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC vs. thiotepa</b>							
Recurrence	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>Doxorubin vs. epirubicin</b>							
Recurrence	3 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>Doxorubicin vs. thiotepa</b>							
Bladder cancer-specific mortality	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Insufficient
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
Progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Insufficient
<b>Epirubicin vs. interferon-alpha</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>3b. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers?</b>	Varied depending on tumor characteristic	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
<b>3c. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, ethnicity, performance status, or medical comorbidities?</b>							
Age, sex, ethnicity, performance status, co-morbidities	No studies	-	-	-	-	-	Insufficient
Recurrence, gemcitabine vs. BCG after progression or recurrence on BCG	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Disease-free survival, MMC vs. gemcitabine maintenance	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>3d. Does the comparative effectiveness of various chemotherapeutic or immunotherapeutic agents differ according to dosing frequency, duration of treatment, and/or the timing of administration relative to TURBT?</b>							
<b>Standard vs. lower dose BCG:</b> Recurrence, progression, mortality, adverse events	6 RCTs	Moderate	Inconsistent	Direct	Precise	Not detected	Low
<b>Maintenance vs. induction BCG:</b> Recurrence, progression, adverse events	2 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
<b>BCG maintenance for 1 vs. 3 years:</b> Recurrence, progression, mortality, adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC single vs. 5 instillations:</b> Recurrence, progression, mortality, adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC induction vs. maintenance:</b> Recurrence, adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC maintenance therapy with increased frequency and number of instillations vs. fewer instillations:</b> Recurrence, progression, adverse events	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
<b>MMC optimized vs. nonoptimized administration:</b> Recurrence, adverse events	2 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Low
<b>Doxorubicin eight weeks vs. two years:</b> Recurrence, progression, adverse events	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>Doxorubicin induction vs. maintenance:</b> Recurrence, progression, mortality, adverse events	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>Doxorubicin prior to vs. after TURBT:</b> Recurrence, adverse events	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>Epirubicin higher vs. lower doses:</b> recurrence, progression, adverse events	3 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
<b>Epirubicin single vs. multiple instillations:</b> Recurrence, progression, bladder cancer mortality, adverse events	3 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
<b>Epirubicin maintenance vs. induction without maintenance:</b> Recurrence, progression, adverse events	2 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
<b>Epirubicin more versus less intensive therapy:</b> Recurrence, adverse events	5 RCTs	Moderate	Inconsistent	Direct	Precise	Not detected	Low
<b>Thiotepa 30 vs. 60 mg:</b> Recurrence, adverse events	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>Interferon alpha-2b, high vs. lower doses:</b> recurrence, progression, resolution of bladder cancer marker lesions	3 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>MMC or doxorubicin on day of TURBT vs. 1 to 2 weeks after TURBT:</b> Recurrence, progression, mortality, adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC or doxorubicin maintenance vs. no maintenance:</b> Recurrence, progression, mortality, adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>4. For patients with high risk non-muscle-invasive bladder cancer treated with TURBT, what is the effectiveness of external beam radiation therapy (either alone or with systemic chemotherapy/immunotherapy) for decreasing mortality or improving other outcomes compared with intravesical chemotherapy/immunotherapy alone or cystectomy?</b>							

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
Mortality, recurrence, progression	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>5. In surveillance of patients treated for non-muscle-invasive bladder cancer, what is the effectiveness of various urinary biomarkers to decrease mortality or improve other outcomes compared with other urinary biomarkers or standard diagnostic methods (cystoscopy, cytology, and imaging)?</b>	No Studies	-	-	-	-	-	Insufficient
a. Does the comparative effectiveness differ according to tumor characteristics, such as histology, stage, grade, size, or molecular/genetic markers?	No Studies	-	-	-	-	-	Insufficient
b. Does the comparative effectiveness differ according to the treatment used (i.e., specific chemotherapeutic or immunotherapeutic agents and/or TURBT)?	No Studies	-	-	-	-	-	Insufficient
c. Does the comparative effectiveness differ according to the length of surveillance intervals?	No Studies	-	-	-	-	-	Insufficient
d. Does the comparative effectiveness differ according to patient characteristics, such as age, sex, or ethnicity?	No Studies	-	-	-	-	-	Insufficient
<b>6. For initial diagnosis or surveillance of patients treated for non-muscle-invasive bladder cancer, what is the effectiveness of blue light or other methods of augmented cystoscopy compared with standard cystoscopy for recurrence rates, progression of bladder cancer, mortality, or other clinical outcomes?</b>							
<b>Fluorescent cystoscopy vs. white light cystoscopy</b>							
Mortality	3 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
Recurrence	13 RCTs	Moderate	Inconsistent	Direct	Precise	Suspected	Low
Progression	6 RCTs	Moderate	Consistent	Direct	Precise	Not detected	Moderate
<b>Narrow band imaging vs. white light cystoscopy</b>							
Recurrence	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
<b>7. What are the comparative adverse effects of various tests for diagnosis and post-treatment surveillance of bladder cancer, including urinary biomarkers, cytology, and cystoscopy?</b>							
<b>Urinary biomarkers:</b> Adverse clinical outcomes	No Studies	-	-	-	-	-	Insufficient
<b>Fluorescent vs. white light cystoscopy:</b> False positives	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>Fluorescent vs. white light cystoscopy:</b> Renal and genitourinary adverse events	2 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>8. What are the comparative adverse effects of various treatments for non-muscle-invasive bladder cancer, including intravesical chemotherapeutic or immunotherapeutic agents and TURBT?</b>							
<b>BCG vs. no intravesical therapy: Local and systemic adverse events</b>	4 RCTs (harms only reported for BCG arm)	High	Inconsistent	Direct	Imprecise	Not detected	Low
<b>Non-BCG intravesical therapies vs. no intravesical therapy: Local and systemic adverse events</b>	Varied depending on intravesical agent	High	Inconsistent	Direct	Imprecise	Not detected	Low for local adverse events, insufficient for systemic adverse events
<b>BCG vs. MMC</b>							
Local adverse events	2 to 6 RCTs	Moderate	Consistent	Direct	Imprecise (precise for cystitis and hematuria)	Not detected	Low (moderate for cystitis and hematuria)
Systemic adverse events	2 to 4 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>BCG vs. BCG plus MMC given sequentially</b>							
Discontinuation of therapy	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG plus MMC given sequentially vs. MMC</b>							
Local adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Systemic adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Discontinuation of therapy	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. doxorubicin</b>							

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
Local adverse events	1 to 3 RCTs	Moderate	Inconsistent or cannot determine	Direct	Imprecise	Not detected	Low (cystitis); insufficient (dysuria and hematuria)
<b>BCG vs. epirubicin</b>							
Local adverse events	1 to 4 RCTs	Moderate	Consistent or cannot determine	Direct	Imprecise	Not detected	Low
Discontinuation of therapy	2 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Insufficient
Systemic adverse events	4 RCTs	Moderate	Consistent	Direct	Imprecise	Not detected	Low
<b>BCG vs. BCG plus epirubicin given sequentially</b>							
Local adverse events	1 to 2 RCTs	Moderate	Consistent or cannot determine	Direct	Imprecise	Not detected	Low
Systemic adverse events	1 to 2 RCTs	Moderate	Consistent or cannot determine	Direct	Imprecise	Not detected	Low
Discontinuation of therapy							
<b>BCG vs. gemcitabine</b>							
Local adverse events	1 to 2 RCTs	Moderate	Consistent or cannot determine	Direct	Imprecise	Not detected	Low
Systemic adverse events	1 to 2 RCTs	Moderate	Consistent or cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. BCG plus gemcitabine given sequentially</b>							
Local adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. interferon alpha-2a</b>							
Local adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Systemic adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. coadministration of BCG and interferon alpha-2b</b>							
Systemic adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>BCG vs. thiotepa</b>							
Local adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Systemic adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC vs. doxorubicin</b>							
Local adverse events	6 RCTs	Moderate	Inconsistent	Direct	Imprecise	Not detected	Insufficient
<b>MMC vs. epirubicin</b>							
Local adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>MMC vs. interferon-alpha</b>							
Local adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Systemic adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low

Key Question Outcome	Study Design Number of Studies (N)	Study Limitations	Consistency	Directness	Precision	Reporting Bias	Strength of Evidence Grade
<b>MMC vs. gemcitabine</b>							
Local adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>Doxorubicin vs. epirubicin</b>							
Local adverse events	1 to 3 RCTs	Moderate	Consistent or cannot determine	Direct	Imprecise	Not detected	Low
<b>Doxorubicin vs. thiotepa</b>							
Local adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>Epirubicin vs. interferon-alpha</b>							
Local adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
Systemic adverse events	1 RCT	Moderate	Cannot determine	Direct	Imprecise	Not detected	Low
<b>8a. How do adverse effects of treatment vary by patient characteristics, such as age, sex, ethnicity, performance status, or medical comorbidities such as chronic kidney disease?</b>	No studies	-	-	-	-	-	Insufficient

## Appendix H. Abbreviations Used in the Appendixes

Abbreviation	Term
AE	Adverse event
5-ALA	5-Aminolevulinic acid
ALT	Alanine transaminase
AOR	Adjusted odds ratio
AST	Aspartate transaminase
AUA	American Urological Association
AUC	Area under the curve
AUROC	Area under the receiver operating curve
BCG	Bacillus Calmette-Guérin
BCG-RIVM	RIVM strain of bacillus Calmette- Guérin
BPH	Benign prostatic hypertrophy
BTA	Bladder tumor antigen
BTA stat	Bladder tumor antigen Polymedco rapid test
BTA TRAK	Bladder tumor antigen quantitative immunoassay
BUN	Blood urea nitrogen
CBC	Complete blood count
CFU	Colony Forming Unit
CI	Confidence interval
CIS	Carcinoma in situ
Cr	Serum creatinine level
CRR	Cumulative recurrence rate
CT scan	Computerized axial tomography
DNA	Deoxyribonucleic acid
EAU	European Association of Urology
ECOG	Eastern Cooperative Oncology Group
EORTC	European Organisation for Research and Treatment of Cancer
FOCA	Fonds Cancer
FISH	Fluorescent in situ hybridization
G0	Grade 0
G1	Grade 1
G2	Grade 2
G3	Grade 3
G4	Grade 4
Gx	Grade unknown
GEM	Gemcitabine
HAL	Hexaminolevulinate
Hgb	Hemoglobin
HR	Hazard ratio
IA	Intra-arterial
IFN-a-2b	Interferon alpha 2b
INH	Isoniazid
IV	Intravenous
IQR	Interquartile range
ISUP	International Society of Urological Pathology
ITT	Intention-to-treat
KQ	Key question
LMP	Low malignant potential
MIBC	Muscle-invasive bladder cancer
MMC	Mitomycin C
MU	Million units
NA	Not applicable
NaCl	Sodium chloride

<b>Abbreviation</b>	<b>Term</b>
NMIBC	Non-muscle-invasive bladder cancer
NMP22	Nuclear matrix protein-22
NPV	Negative predictive value
NR	Not reported
NRCT	Nonrandomized controlled trial
NS	Not significant
OncoTICE BCG	OncoTICE strain of bacillus Calmette-Guérin
PBO	Placebo
PPD	Purified protein derivative
PPV	Positive predictive value
pT1	Tumor stage 1 determined by pathology
pT1b	Tumor stage 1b determined by pathology
pT2	Tumor stage 2 determined by pathology
pTis	Tumor in situ determined by pathology
RCT	Randomized controlled trial
RFS	Recurrence-free survival
RNA	Ribonucleic acid
RR	Risk ratio
SD	Standard deviation
SWOG	Southwest Oncology Group
T0	Tumor stage 0
T1	Tumor stage 1
T2	Tumor stage 2
T2a	Tumor stage 2a
T3	Tumor stage 3
T3a	Tumor stage 3a
T3b	Tumor stage 3b
T4	Tumor stage 4
TCC	Transitional cell carcinoma
Tis	Carcinoma in situ
TUC	Transurethral coagulation
TURBT	Transurethral resection of bladder tumor
Tx	Tumor stage unknown
UK	United Kingdom
UTI	Urinary tract infection
WBC	White blood cell
WHO	World Health Organization
