This report is based on research conducted by the Brown Evidence-based Practice Center (EPC) under contract to the Agency for Healthcare Research and Quality (AHRQ), Rockville, MD (Contract No. 290-2015-00002-I). The report is sponsored by the National Institutes of Health Office of Dietary Supplements (NIH/ODS). The findings and conclusions in this document are those of the authors, who are responsible for its contents; the findings and conclusions do not necessarily represent the views of AHRQ or NIH/ODS. Therefore, no statement in this report should be construed as an official position of AHRQ, NIH/ODS, or the U.S. Department of Health and Human Services.

None of the investigators have any affiliations or financial involvement that conflicts with the material presented in this report.

The information in this report is intended to help health care decisionmakers-patients and clinicians, health system leaders, and policymakers, among others-make well-informed decisions and thereby improve the quality of health care services. This report is not intended to be a substitute for the application of clinical judgment. Anyone who makes decisions concerning the provision of clinical care should consider this report in the same way as any medical reference and in conjunction with all other pertinent information, i.e., in the context of available resources and circumstances presented by individual patients.

This report is made available to the public under the terms of a licensing agreement between the author and the Agency for Healthcare Research and Quality. This report may be used and reprinted without permission except those copyrighted materials that are clearly noted in the report. Further reproduction of those copyrighted materials is prohibited without the express permission of copyright holders.

AHRQ or U.S. Department of Health and Human Services endorsement of any derivative products that may be developed from this report, such as clinical practice guidelines, other quality enhancement tools, or reimbursement or coverage policies, may not be stated or implied.

This report may periodically be assessed for the currency of conclusions. If an assessment is done, the resulting surveillance report describing the methodology and findings will be found on the Effective Health Care Program Web site at www.effectivehealthcare.ahrq.gov. Search on the title of the report.

Persons using assistive technology may not be able to fully access information in this report. For assistance contact EffectiveHealthCare@ahrq.hhs.gov.

## Preface

The Agency for Healthcare Research and Quality (AHRQ), through its Evidence-based Practice Centers (EPCs), sponsors the development of systematic reviews to assist public- and private-sector organizations in their efforts to improve the quality of health care in the United States. These reviews provide comprehensive, science-based information on common, costly medical conditions, and new health care technologies and strategies.

Systematic reviews are the building blocks underlying evidence-based practice; they focus attention on the strength and limits of evidence from research studies about the effectiveness and safety of a clinical intervention. In the context of developing recommendations for practice, systematic reviews can help clarify whether assertions about the value of the intervention are based on strong evidence from clinical studies. For more information about AHRQ EPC systematic reviews, see www.effectivehealthcare.ahrq.gov/reference/purpose.cfm.

AHRQ expects that these systematic reviews will be helpful to health plans, providers, purchasers, government programs, and the health care system as a whole. Transparency and stakeholder input are essential to the Effective Health Care Program. Please visit the Web site (www.effectivehealthcare.ahrq.gov) to see draft research questions and reports or to join an email list to learn about new program products and opportunities for input.

If you have comments on this systematic review, they may be sent by mail to the Task Order Officer named below at: Agency for Healthcare Research and Quality, 5600 Fishers Lane, Rockville, MD 20857, or by email to epc@ahrq.hhs.gov.

## Technical Expert Panel

In designing the study questions and methodology at the outset of this report, the EPC consulted several technical and content experts. Broad expertise and perspectives were sought. Divergent and conflicted opinions are common and perceived as healthy scientific discourse that results in a thoughtful, relevant systematic review. Therefore, in the end, study questions, design, methodologic approaches, and/or conclusions do not necessarily represent the views of individual technical and content experts.

Technical Experts must disclose any financial conflicts of interest greater than \$10,000 and any other relevant business or professional conflicts of interest. Because of their unique clinical or content expertise, individuals with potential conflicts may be retained. The TOO and the EPC work to balance, manage, or mitigate any potential conflicts of interest identified.

The list of Technical Experts who provided input to this report follows:

Philip Calder, Ph.D., R.Nutr.
University of Southampton
Southampton, United Kingdom
William R. Harlan, M.D.*
Associate Director for Disease Prevention (Ret)
National Institutes of Health
Chevy Chase, MD
Van S. Hubbard, M.D., Ph.D.
Current:
Rear Admiral, U.S. Public Health Service
(Ret)
At time of review:
National Institutes of Health

* Provided input on Draft Report.

## Director

Division of Nutrition Research Coordination
Associate Director for Nutritional Sciences
National Institute of Diabetes and Digestive and Kidney Diseases
Washington, DC
Charlotte Pratt, Ph.D., R.D.
National Institutes of Health
National Heart, Lung and Blood Institute Washington, DC

Lu Wang, M.D., Ph.D.*
Harvard Medical School
Brigham and Women’s Hospital
Boston, MA

## Peer Reviewers

Prior to publication of the final evidence report, EPCs sought input from independent Peer Reviewers without financial conflicts of interest. However, the conclusions and synthesis of the scientific literature presented in this report do not necessarily represent the views of individual reviewers.

Peer Reviewers must disclose any financial conflicts of interest greater than \$10,000 and any other relevant business or professional conflicts of interest. Because of their unique clinical or content expertise, individuals with potential nonfinancial conflicts may be retained. The TOO and the EPC work to balance, manage, or mitigate any potential nonfinancial conflicts of interest identified.

The list of Peer Reviewers follows:

Ingeborg A. Brouwer, Ph.D., M.Sc.
Vrije Universiteit Amsterdam
Amsterdam, The Netherlands

David A. Lathrop, Ph.D.
National Institutes of Health
National Heart, Lung and Blood Institute
Washington, DC

JoAnn E. Manson, M.D., M.P.H., Dr.P.H. Harvard Medical School
Harvard T.H. Chan School of Public Health Brigham and Women's Hospital Boston, MA

Hildegard Przyrembel, M.D., Ph.D.
Bundesinstitut für Risikobewertung (Federal Institute for Risk Assessment)
Berlin, Germany

## Omega-3 Fatty Acids and Cardiovascular Disease: An Updated Systematic Review <br> Structured Abstract

Background. The effect and association of omega-3 fatty acids (n-3 FA) intake and biomarker levels with cardiovascular (CV) clinical and intermediate outcomes remains controversial. We update prior Evidence Reports of n-3 FA and clinical and intermediate CV disease (CVD) outcomes.

Objectives. Evaluate the effect of n-3 FA on clinical and selected intermediate CV outcomes and the association of n-3 FA intake and biomarkers with CV outcomes. The n-3 FA under review include eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA), docosapentaenoic acid (DPA), stearidonic acid (SDA), and alphalinolenic acid (ALA).

Data sources. MEDLINE ${ }^{\circledR}$, Embase ${ }^{\circledR}$, the Cochrane Central Register of Controlled Trials, Cochrane Database of Systematic Reviews, and CAB Abstracts from 2000 or 2002 to June 8, 2015, and eligible studies from the original reports and relevant existing systematic reviews.

Review methods. We included randomized controlled trials (RCTs) of any n-3 FA intake compared to no, lower, or other n-3 FA intake with an outcome of interest conducted in healthy adults, those at risk for CVD, or those with CVD. We also included prospective observational studies of the association between baseline n-3 FA intake or biomarker level and followup outcomes. We required 1 year or more of followup for clinical outcomes and 4 weeks for intermediate outcomes (blood pressure [BP] and lipids).

Results. From 11,440 citations (from electronic literature searches and existing systematic reviews), 829 abstracts met basic eligibility criteria; 61 RCTs and 37 longitudinal observational studies (in 147 articles) were included. Most RCTs and observational studies had few risk-ofbias concerns.

Total n-3 FA: There is low strength of evidence (SoE) of no association between total n-3 FA intake and stroke death or myocardial infarction. There is insufficient evidence for other outcomes.

Marine oils, total: There is moderate to high SoE that higher marine oil intake lowers triglycerides ( Tg ), raises high density lipoprotein cholesterol (HDL-c), and lowers the ratio of total cholesterol to HDL-c but raises low density lipoprotein cholesterol (LDL-c); also that higher marine oil intake does not affect major adverse CV events, all-cause death, sudden cardiac death, coronary revascularization, atrial fibrillation, or BP. There is low SoE of associations between higher marine oil intake and decreased risk of CVD death, coronary heart disease (CHD), myocardial infarction, ischemic stroke, and congestive heart failure (CHF). There is low SoE of no association with CHD death, total stroke, hemorrhagic stroke, or angina pectoris. There is insufficient evidence for other outcomes.

Marine oil FA individually: There is low SoE of no associations between EPA or DHA intake (separately) and CHD, and between EPA or DPA and atrial fibrillation. There is low SoE of no association between EPA biomarkers and atrial fibrillation, but moderate SoE of no effect of purified DHA supplementation on BP or LDL-c. There is insufficient evidence for other specific marine oil FA and outcomes.

ALA: There is moderate SoE of no effect of ALA intake on BP, LDL-c, HDL-c, or Tg. There is low SoE of no association between ALA intake or biomarker level and CHD, CHD death, atrial fibrillation, and CHF. There is insufficient evidence for other outcomes.

Other n-3 FA analyses: There is insufficient evidence comparing n-3 FA with each other or for SDA.

Subgroup analyses: Nineteen of 22 studies found no interaction of sex on any effect of n-3 FA. Likewise, 19 of 20 studies found no differential effect by statin co-use. Within 16 studies evaluating diabetes subgroups, 2 found statistically significant beneficial effects of n-3 FA in those with diabetes but not in those without diabetes, but no test of interaction was reported.

Conclusions. The 61 RCTs mostly compared marine oil supplements with placebo on CVD outcomes in populations at risk for CVD or with CVD, while the 37 observational studies mostly examined associations between various individual n-3 FA and long-term CVD events in generally healthy populations. Compared with the prior report on n-3 FA and CVD, there is more robust RCT evidence on ALA and on clinical CV outcomes; also, by design there are newly added data on associations between n-3 FA biomarkers and CV outcomes. However, conclusions regarding the effect of n-3 FA intake on CV outcomes or associations with outcomes remain substantially unchanged. Marine oils statistically significantly raise HDL-c and LDL-c by similar amounts ( $\leq 2 \mathrm{mg} / \mathrm{dL}$ ), while lowering Tg in a dose-dependent manner, particularly in individuals with elevated Tg; they have no significant effect on BP. ALA has no significant effect on intermediate outcomes. Limited data were available from RCTs on the effect of n-3 FA on clinical CVD outcomes. Observational studies suggest that higher marine oil intake (including from dietary fish) is associated with lower risk of several CVD outcomes. No clear differences in effects or associations were evident based on population, demographic features, or cointerventions. Future RCTs would be needed to establish adequate evidence of the effect of n3 FA on CVD outcomes or to clarify differential effects in different groups of people. However, future trials are unlikely to alter conclusions about the effects of n-3 FA supplementation on intermediate cardiovascular outcomes (BP, LDL-c, HDL-c, or Tg).

## Executive Summary

## Introduction

Since the first ecological study published in the late 1970s noted a relatively low cardiovascular (CV) mortality in a Greenland Eskimo population with high fish consumption, ${ }^{1}$ there have been hundreds of observational studies and clinical trials conducted to evaluate the effect of omega-3 fatty acids (n-3 FA) on CV disease (CVD) and its risk factors and intermediate markers. The n-3 FA (including alphalinolenic acid [ALA], stearidonic acid [SDA], eicosapentaenoic acid [EPA], docosapentaenoic acid [DPA], and docosahexaenoic acid [DHA]) are a group of long-chain and very-long-chain polyunsaturated fatty acids (PUFA) that are substrates for the synthesis of eicosanoids and are important components of cell membranes that impact fluidity. Major dietary sources of ALA include soybean and canola oils, some nuts, and flaxseed. The major dietary sources of EPA and DHA are fish, other marine life, and marinederived supplements. There is no naturally occurring source of SDA that, per serving, provides amounts of n-3 FA approaching levels (of EPA and DHA) present in oily fish. Naturally occurring sources of SDA-hemp and echium seed oils-are not consumed by the general population.

Since the publication of the original Agency for Healthcare Research and Quality (AHRQ) n-3 FA systematic reviews in $2004^{2,3}$ the topic of n-3 FA and CVD has remained controversial. This topic has been evaluated by several expert panels considering whether recommendations or reference values for intakes of EPA and DHA were warranted, either through naturally occurring sources of n-3 FA (e.g., fish consumption) and/or through the use of dietary supplements and fortified foods. ${ }^{4-7}$ In 2002, the Institute of Medicine (IOM) considered the evidence inadequate to establish an estimated average requirement for n-3 FA. ${ }^{5}$ For healthy adults, the adequate intake values for ALA are $1.1 \mathrm{~g} / \mathrm{d}$ for females and $1.6 \mathrm{~g} / \mathrm{d}$ for males. ${ }^{5}$ After evaluating evidence linking the very-long-chain n-3 FA-EPA and DHA-to coronary heart disease (CHD, also known as coronary artery disease) and stroke, the IOM panel suggested that n-3 FA may provide beneficial health effects with respect to CHD and stroke; the acceptable macronutrient distribution range (a range of intakes that is associated with reduced risk of chronic diseases while providing adequate intakes of essential nutrients) for ALA was set at 0.6 to 1.2 percent of energy (roughly equivalent to 1 to $3 \mathrm{~g} / \mathrm{d}$ ), where 10 percent of this range can be consumed as EPA and/or DHA. ${ }^{5}$ For comparison, the mean intake of ALA in the United States has been estimated at 0.6 percent of energy intake (standard deviation $1.0 \%$ ), ${ }^{8}$ equivalent to approximately $1.4 \mathrm{~g} / \mathrm{d}$. This intake level is fairly consistent across developed countries (0.3-1.0\% of energy). However, estimated EPA and DHA intake in the United States are only $0.05 \mathrm{~g} / \mathrm{d}$ and $0.08 \mathrm{~g} / \mathrm{d}$, respectively. ${ }^{8}$ In contrast, mean intake in South Korea is $0.4 \mathrm{~g} / \mathrm{d}$ of EPA and DHA, combined. Three other expert reports evaluated the potential health benefits of fish and seafood consumption. ${ }^{4,6,7}$ Based primarily on the availability of observational study data, these panels consistently suggested that regular consumption of fish and seafood is associated with lower risk of CHD and cardiac death. These recommendations were based primarily on assumptions of benefits from EPA and DHA and their content in fish and seafood. However, determination of n3 FA intake is problematic, both for population recommendations and in regards to research. In practice, all nutrients are quantified using a nutrient database, e.g., the U.S. Department of Agriculture National Nutrient Database for Standard Reference (http://ndb.nal.usda.gov/). The quantity of a nutrient is then estimated by the standard amount of nutrients in foods that are indexed in the nutrient database multiplied by the amount and frequency of the food
consumption. However, n-3 FA in foods are not well estimated in the nutrient database and questionnaires commonly do not ask about cooking oils or dressings and may not ask about supplements (so that n-3 FA intake is estimated only from fish consumption); therefore quantification of n-3 FA intake from food frequency questionnaires is poor. Furthermore, some questionnaires do not include portion size, so further estimation or extrapolation of intake is required.

There have been secular trends in the prevention and treatment of CVD over the past several decades, particularly since the 2004 AHRQ reports on n-3 FA and CVD. These trends may have had an important impact on the potential effect or association between n-3 FA intake and CVD outcomes. Important among these trends are the lower rates of cardiac and cerebrovascular disease, concomitant with higher rates of treatment and control of dyslipidemia and hypertension. For at least the past 20 years American adults are increasingly likely to be treated with statins, antihypertensives, and low-dose aspirin. All of these pharmacologic interventions act on metabolic and biochemical pathways that n-3 FA also impact and this confounding may impact the purported CV benefits of n-3 FA, including lipid metabolism, blood pressure (BP) and vascular homeostasis, and inflammatory and coagulation pathways. These treatment trends may have contributed to the lower population-level CV benefit of higher n-3 FA intake because the underlying risk of CVD is now lower, hence, diminishing the potential impact of n-3 FA intake. Furthermore, diagnostic criteria for CVD events (e.g., myocardial infarction [MI]) and CV risk factors (e.g., metabolic syndrome) have been refined over time which may make older studies less applicable in terms of their outcomes and populations.

There are ongoing concerns in the scientific community regarding systematic biases and random errors in the determination of intakes of n-3 FA from dietary and supplement sources, using currently available assessment tools. Nutrient biomarkers can provide an objective measure of dietary status. ${ }^{9}$ However, the correspondence between intake and biomarker concentration not only reflects recent intake but also subsequent metabolism. Current biomarkers used to estimate n-3 FA intake include ALA, EPA, DHA, and, less frequently, SDA and DPA, measured in adipose tissue, erythrocytes, plasma, or plasma phospholipids. ${ }^{9-11}$ Adipose tissue FA are thought to reflect long-term intake, erythrocyte FA are thought to reflect intake over the previous 120 days, and plasma FA are thought to reflect more recent intake. ${ }^{10}$

## Scope of the Review

The National Institutes of Health's Office of Dietary Supplements (ODS) has a long history of commissioning AHRQ-based systematic reviews and research methodology reports for nutrition-related topics (http://ods.od.nih.gov/Research/Evidence-Based_Review_Program.aspx). The purpose of the current ODS-sponsored systematic review is twofold: 1) to update earlier reviews of the state-of-the science on the topic of the effects of n-3 FA on CVD ${ }^{3}$ and selected CVD risk factors and intermediate markers of CVD, ${ }^{2}$ and 2) to collect additional information that will enhance the usefulness of this report for policy and clinical applications. This review updates the outcomes reported in the previous review and expands the scope to include additional CVD outcomes (peripheral vascular disease, congestive heart failure (CHF), and arrhythmias); it updates BP and plasma lipid outcomes and adds incident hypertension; it adds associations between biomarkers of n-3 FA intake and outcomes. The primary target audience for this report is clinical and nutrition researchers and policymakers, including ODS and panels revising dietary intake recommendations.

## Key Questions

The Key Questions address issues of efficacy (i.e., causal relationships from trials), as well as associations (i.e., prospective observational cohort study associations of n-3 FA intake and/or biomarkers with long-term outcomes; or biomarker associations reported in randomized controlled trials [RCTs]). Compared with the Key Questions from the 2004 reports, the current Key Questions expand the scope of the review to include additional CV outcomes (BP, CHF, and arrhythmias), focus on the intermediate outcomes plasma lipids and BP, add the intermediate outcome hypertension, and include associations between biomarkers of intake and outcomes.

1. What is the efficacy or association of n-3 FA (EPA, DHA, EPA+DHA, DPA, SDA, ALA, or total n-3 FA) exposures in reducing CVD outcomes (incident CVD events, including all-cause death, CVD death, nonfatal CVD events, new diagnosis of CVD, peripheral vascular disease, CHF, major arrhythmias, and hypertension diagnosis) and specific CVD risk factors (BP, key plasma lipids)?

- What is the efficacy or association of n-3 FA in preventing CVD outcomes in people
o Without known CVD (primary prevention)
o At high risk for CVD (primary prevention), and
o With known CVD (secondary prevention)?
- What is the relative efficacy of different n-3 FA on CVD outcomes and risk factors?
- Can the CVD outcomes be ordered by strength of intervention effect of $n-3$ FA?

2. n-3 FA variables and modifiers:

- How does the efficacy or association of n-3 FA in preventing CVD outcomes and with CVD risk factors differ in subpopulations, including men, premenopausal women, postmenopausal women, and different age or race/ethnicity groups?
- What are the effects of potential confounders or interacting factors-such as plasma lipids, body mass index, BP, diabetes, kidney disease, other nutrients or supplements, and drugs (e.g., statins, aspirin, diabetes drugs, hormone replacement therapy)?
- What is the efficacy or association of different ratios of n-3 FA components in dietary supplements or biomarkers on CVD outcomes and risk factors?
- How does the efficacy or association of n-3 FA on CVD outcomes and risk factors differ by ratios of different n-3 FA—DHA, EPA, and ALA, or other n-3 FA?
- How does the efficacy or association of n-3 FA on CVD outcomes and risk factors differ by source (e.g., fish and seafood, common plant oils (e.g., soybean, canola), fish oil supplements, fungal-algal supplements, flaxseed oil supplements)?
- How does the ratio of n-6 FA to n-3 FA intakes or biomarker concentrations affect the efficacy or association of n-3 FA on CVD outcomes and risk factors?
- Is there a threshold or dose-response relationship between n-3 FA exposures and CVD outcomes and risk factors? Does the study type affect these relationships?
- How does the duration of intervention or exposure influence the effect of $n-3$ FA on CVD outcomes and risk factors?
- What is the effect of baseline n-3 FA status (intake or biomarkers) on the efficacy of $n-3$ FA intake or supplementation on CVD outcomes and risk factors?

## 3. Adverse events:

- What adverse effects are related to n-3 FA intake (in studies of CVD outcomes and risk factors)?
- What adverse events are reported specifically among people with CVD or diabetes (in studies of CVD outcomes and risk factors)?

## Analytic Framework

To guide the assessment of studies that examine the association between n-3 FA intake and CV outcomes, the analytic framework maps the specific linkages associating the populations of interest, exposures, modifying factors, and outcomes of interest (Figure A). The framework graphically presents the key components of well-formulated study questions:

1. Who are the participants (i.e., what is the population and setting of interest, including the diseases or conditions of interest)?
2. What are the interventions?
3. What are the outcomes of interest (intermediate and health outcomes)?
4. What study designs are of value?

Specifically, this analytic framework depicts the chain of logic that evidence must support to link the intervention (exposure to n-3 FA) to improved health outcomes.

Figure A. Analytic framework for omega-3 fatty acid exposure and cardiovascular disease

Legends: This framework concerns the effect of n-3 FA exposure (as a supplement or from food sources) on CVD and CV risk factors. Populations of interest are noted in the top rectangle, exposure in the oval, outcomes in the rounded rectangles, and effect modifiers in the hexagon.

* Specifically, CV medications, statins, antihypertensives, diabetes medications, hormone replacement regimens. $\dagger$ Systolic blood pressure, diastolic blood pressure, mean arterial pressure, high density lipoprotein cholesterol (HDLc), low density lipoprotein cholesterol (LDL-c), total/HDL-c ratio, LDL-c/HDL-c ratio, triglycerides. $\ddagger$ Many other intermediate outcomes are likely in the causal pathway between n-3 FA intake and CV outcome, but only blood pressure and plasma lipids were included in the review.

Abbreviations: ALA = alphalinolenic acid, CHD = coronary heart disease, CHF = congestive heart failure, CKD = nondialysis-dependent chronic kidney disease, CMS = cardiometabolic syndrome, CVA = cerebrovascular accident (stroke), CVD = cardiovascular disease, DHA = docosahexaenoic acid, DM = diabetes mellitus, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, FA = fatty acid, HTN = hypertension, MI = myocardial infarction, $\mathrm{n}-3=$ omega-3, $\mathrm{n}-6=$ omega- $6, \mathrm{PCI}=$ percutaneous coronary intervention, SDA $=$ stearidonic acid.

## Methods

The present review evaluates the effects of, and the associations between, n-3 FA (EPA, DPA, ALA and n-3 FA biomarkers) and CVD outcomes. The Brown Evidence-based Practice Center (EPC) conducted the review based on a systematic review of the published scientific literature using established methodologies as outlined in the AHRQ Methods Guide for Effectiveness and Comparative Effectiveness Reviews (Methods Guide). ${ }^{12}$

The review was conducted in parallel with a systematic review of n-3 FA and child and maternal health, conducted by another EPC. Several aspects of the review were coordinated, including eligibility criteria and search strategies regarding interventions and exposures structure of the reviews, as well as assessments of the studies’ risk of bias, strength of the bodies of evidence, and extraction of study characteristics needed to assess causality.

We convened a Technical Expert Panel (TEP) to help refine the research questions and protocol, including the Key Questions, analytic framework, study eligibility criteria, literature search, and analysis plans.

## Literature Search

## Search Strategy

We conducted literature searches of studies in MEDLINE®, both the Cochrane Central Trials Registry ${ }^{\circledR}$ and Cochrane Database of Systematic Reviews ${ }^{\circledR}$, Embase ${ }^{\circledR}$, and CAB Abstracts ${ }^{\circledR}$ from 2002 to 8 June 2015 (to overlap with the last search run for the 2004 reviews). We searched publications back to 2000 for the newly added outcomes and for biomarkers of $n-3$ FA intake. We also rescreened and included all studies from the original reviews that met current eligibility criteria. Titles and abstracts were independently double-screened to identify articles relevant to each Key Question. We also reviewed reference lists of related systematic reviews for other potentially eligible studies.

## Inclusion and Exclusion Criteria

For all Key Questions, the eligibility criteria are:
Populations

- Healthy adults ( $\geq 18$ years) without CVD or with low to intermediate risk for CVD
- Adults at high risk for CVD (e.g., with diabetes, cardiometabolic syndrome, hypertension, dyslipidemia, nondialysis chronic kidney disease)
- Adults with clinical CVD (e.g., history of myocardial infarction [MI], angina, stroke, arrhythmia)
- Exclude populations chosen for having a non-CVD or nondiabetes-related disease (e.g., cancer, gastrointestinal disease, rheumatic disease, dialysis)

Interventions/Exposures

- n-3 FA supplements
- n-3 FA supplemented foods (e.g., eggs)
- n-3 FA content in diet
- Biomarkers of n-3 FA intake
- n-3 FA content of food or supplements must have been explicitly quantified (by any method). Therefore, studies, such as those of fish diet where only servings per week were defined or Mediterranean diet studies without quantified n-3 FA, were excluded. The n-3 FA quantification could be of total n-3 FA, of a specific n-3 FA (e.g., ALA, purified DHA) or of combined long-chain n-3 FA (EPA, DHA, and DPA, regardless of source; hereafter referred to as marine oils).
- Exclude mixed interventions of n-3 FA and other dietary or supplement differences (e.g., n-3 FA and vitamin E versus placebo; n-3 FA as part of a low-fat diet versus usual diet). However, factorial design (and other) studies that compared (for example) n-3 FA versus control, with or without another intervention (e.g., statins) were included.
- Exclude n-3 FA dose $\geq 6 \mathrm{~g} / \mathrm{d}$
- Exclude weight-loss interventions

## Comparators

- Placebo or no n-3 FA intervention
- Different n-3 FA source intervention
- Different n-3 FA concentration intervention
- Different n-3 FA dietary exposure (e.g., comparison of quantiles)
- Different n-3 FA biomarker levels (e.g., comparison of quantiles)

## Outcomes

- All-cause death
- Cardiovascular (CV), cerebrovascular, and peripheral vascular events:
o Fatal vascular events (e.g., due to MI, stroke)
o Total incident vascular events (e.g., MI, stroke, transient ischemic attack, unstable angina, major adverse CV events [MACE]; total events include fatal and nonfatal events; total stroke includes ischemic and hemorrhagic stroke)
o Coronary heart disease (CHD, also known as coronary artery disease), new diagnosis
o Congestive heart failure (CHF), new diagnosis
o Cerebrovascular disease, new diagnosis
o Peripheral vascular disease, new diagnosis
o Ventricular arrhythmia, new diagnosis, including sudden cardiac death [SCD]
o Supraventricular arrhythmia (including atrial fibrillation [AFib]), new diagnosis
o Major vascular interventions/procedures (e.g., revascularization, thrombolysis, lower extremity amputation, defibrillator placement)
- Major CVD risk factors (intermediate outcomes):
o Blood pressure (BP) (new-onset hypertension, systolic, diastolic, and mean arterial pressure [MAP])
o Key plasma lipids (i.e., high density lipoprotein cholesterol [HDL-c], low density lipoprotein cholesterol [LDL-c], total/HDL-c ratio, LDL-c/HDL-c ratio, triglycerides [Tg])
- Adverse events (e.g., bleeding, major gastrointestinal disturbance), only from intervention studies of supplements

## Timing

- Clinical outcomes, including new-onset hypertension (all study designs): $\geq 1$ year followup (and intervention duration, as applicable)
- Intermediate outcomes (BP and plasma lipids) (all study designs): $\geq 1$ month followup
- Adverse events (all study designs): no minimum followup

Setting

- Community-dwelling (noninstitutionalized) individuals

## Study Design

- RCTs (all outcomes)
- Randomized cross-over studies (BP and plasma lipids, adverse events)
- Prospective nonrandomized comparative studies (clinical outcomes, adverse events)
- Prospective cohort (single group) studies, where groups were compared based on n-3 FA intake or intake biomarker values (clinical outcomes). Observational studies must have reported multivariate analyses.
- Exclude: Retrospective or case control studies or cross-sectional studies (but include prospective nested case control studies). Studies must have had measures of intake prior to outcome.
- Minimum sample sizes

Due to the very large number of potentially eligible studies (more than 400), we applied arbitrary thresholds based on sample size, followup duration, and whether subgroup or interaction analyses were reported. These were designed to give preference to larger studies with longer followup duration or that reported interaction analyses of interest.
o RCTs

- We aimed for a minimum of about 25 RCTs for each of the BP and plasma lipid outcomes. We preferentially included RCTs that reported relevant subgroup, interaction, or factorial analyses.
- For RCTs with BP or lipid outcomes with subgroup, interaction, or factorial analyses, we included parallel design RCTs with a minimum of 30 participants per arm, factorial RCTs with a minimum of 30 participants per n-3 FA intervention, and crossover trials with a minimum of 20 participants.
- For RCTs with lipid outcomes without subgroup analyses, we included parallel design RCTs with a minimum of 200 participants per arm, factorial RCTs with a minimum of 200 participants per n-3 FA intervention, and crossover trials with a minimum of 100 participants.
- For RCTs with BP outcomes without subgroup analyses, if followup was $\geq 6$ months, we included all RCTs; if followup was $<6$ months ( $\geq 1$ month), we included parallel design RCTs with a minimum of 80 participants per arm, factorial RCTs with a minimum of 80 participants per n-3 FA intervention, and crossover trials with a minimum of 40 participants.
- For RCTs with CVD event outcomes, we included all RCTs with at least 10 participants per arm.
o Longitudinal observational studies
- We aimed for a minimum of about 10 observational studies for each broad clinical outcome (see bullets below) and also for dietary marine oils, dietary ALA, marine oil biomarkers, and ALA biomarkers.
- For cardiac event outcomes, we included observational studies with at least 10,000 participants.
- For death outcomes, we included observational studies with at least 10,000 participants.
- For stroke event outcomes, we included observational studies with at least 3000 participants.
- For arrhythmia event outcomes, we included observational studies with at least 2000 participants.
- For CHF event outcomes, we included observational studies with at least 700 participants.
- For peripheral vascular disease event, incident hypertension, MACE, and revascularization outcomes, we included observational studies with at least 500 participants.
- We screened smaller sample size observational studies (starting with the largest studies) to include additional studies of ALA biomarkers, regardless of the outcomes analyzed.
o In all instances, if a study met eligibility criteria for any outcome, we extracted all outcomes of interest from that study; therefore, there are multiple instances of studies being included for an outcome even though the study might not have met study size criteria for that specific outcome.
- English language publications
- Peer reviewed publications

## Quality (Risk of Bias) Assessment of Individual Studies

We assessed the methodological quality of each study based on predefined criteria. For RCTs, we used the Cochrane risk of bias tool ${ }^{13}$ and for observational studies we used relevant questions from the Newcastle Ottawa Scale. ${ }^{14}$ Additionally, we included nutrition study specific risk of bias questions (e.g., related to uncertainty of dietary assessment measurements). ${ }^{15-17}$

## Data Synthesis

Statistical analyses were conducted in Stata version 13.1 (StataCorp, College Station, Texas). We conducted random effects model meta-analyses of comparative studies (i.e., RCTs) if, for each set of studies with the same outcome and intervention and comparator pair, there were at least six studies. We meta-analyzed multivariate observational cohorts when at least four cohorts analyzed the same n-3 FA, measure, and outcome.

## Strength of the Body of Evidence

We graded the strength of the body of evidence per the AHRQ Methods Guide on assessing the strength of evidence for each outcome. ${ }^{18}$ The strength-of-evidence dimensional
ratings are summarized in Evidence Profile tables that detail our reasoning behind the overall strength of evidence rating.

## Peer Review and Public Commentary

A draft version of this report was reviewed by a panel of expert reviewers and the general public. The reviewers were either directly invited by the EPC or offered comments through a public review process. Revisions of the draft were made, where appropriate, based on their comments. The draft and final reports were also reviewed by the Task Order Officer and an Associate Editor from another EPC. However, the findings and conclusions are those of the authors, who are responsible for the contents of the report.

## Results

The literature searches yielded 11,440 citations. Reference lists from existing systematic reviews yielded 203 additional citations (which mostly represented articles published before 2002). Of these, 829 abstracts met basic eligibility criteria. As described in the Methods chapter of the full report (under Study Selection), using an evidence map process, we selected 463 articles for full text review, of which 147 articles met eligibility criteria, representing 61 RCTs (in 82 articles) and 37 longitudinal observational studies (in 65 articles).

Across RCTs, the studies generally had few risk of bias concerns. Among the 61 RCTs, 23 (38\%) had no high risk of bias / study quality limitations; an additional 26 RCTs (43\%) had one risk of bias limitation and 6 (10\%) had two risk of bias limitations. None of the remaining 6 RCTs (10\%) had more than four study limitations (of 10 explicitly assessed potential limitations). The most common risk of bias limitation was a lack of intention-to-treat analyses; 12 RCTs (20\%) clearly did not conduct intention-to-treat analyses (one of these conducted an intention-to-treat analysis for the outcome death, but not for lipid outcomes); 12 additional RCTs (20\%) were unclear whether intention-to-treat analyses were conducted. Ten RCTs (16\%) did not blind study participants (and 4 additional, 7\%, were unclear whether they blinded participants), often because the intervention was dietary and could not be blinded. However, only 7 RCTs (11\%) clearly did not blind outcome assessors (nine additional RCTs, $14 \%$, were unclear regarding outcome assessor blinding). Attrition bias, primarily due to dropout rates greater than 20 percent, was present in 9 RCTs (15\%). Other potential biases were less common.

Across the observational studies, there were fairly few risk of bias concerns. Nine of 37 studies (24\%) had no high risk of bias concerns; 20 (54\%) had only a single high risk of bias concern (of 7 explicitly assessed potential limitations) and 6 (16\%) had two risk of bias concerns. The 2 remaining studies (5\%) had three risk of bias concerns. No study was deemed to have high risk of selection bias (regarding whether the outcome was present at baseline) and all adequately adjusted for confounders. The majority of studies used a dietary assessment tool that did not include dietary supplements (18 of 29 applicable studies; 62\%); an additional 4 studies (14\%) were unclear whether dietary supplements were used. Sixteen studies (43\%) did not adequately reported baseline nutrient exposures. Bias due to lack of outcome assessor blinding was infrequent (3 studies [8\%]; 4 studies [11\%] were unclear), as was attrition bias (1 study [3\%]; 4 studies [11\%] were unclear). All observational studies reported multivariate analyses (this was an eligibility criterion).

The trials of clinical outcomes were almost all conducted in populations at increased risk of CVD, largely related to dyslipidemia, or with CVD. The trials that reported intermediate outcomes (BP and lipoproteins), were conducted in generally healthy, at-risk, and CVD
populations. The observational studies, in contrast, were almost all conducted in general (unrestricted by CVD or risk factors) or healthy populations. One observational study evaluated BP; none evaluated lipids.

In this Executive Summary, we present the results by n-3 FA, first summarizing the strength of evidence across studies, then separately summarizing the clinical CV event outcomes from RCTs, the intermediate CV outcomes from RCTs, the observational study associations with n-3 FA intake, and the observational study associations with n-3 FA biomarkers. We also include the findings regarding adverse events and a summary directly addressing each Key Question. For the interested reader, the main report primarily summarizes the study results first by outcome, then by n-3 FA, then by study design. A listing of effects or associations of n-3 FA and outcomes by the strength of evidence supporting the findings is included at the start of the Discussion section.

## Summary by n-3 FA

The trials of clinical outcomes were almost all conducted in populations at increased risk of CVD, largely related to dyslipidemia, or with CVD. The trials that reported intermediate outcomes (BP and lipoproteins), were conducted in generally healthy, at-risk, and CVD populations. The observational studies, in contrast, were almost all conducted in general (unrestricted by CVD or risk factors) or healthy populations. One observational study evaluated BP ; none evaluated lipids.

## Total n-3 FA (ALA+EPA+DHA)

Overall, there is insufficient evidence regarding the effect of or association between total $\mathrm{n}-3$ FA (combined ALA and marine oils) and clinical or intermediate outcomes. There is low strength of evidence of no association between total n-3 FA intake and stroke death, and total (fatal and nonfatal) MI (each association based on longitudinal observational studies of dietary intake). For both outcomes, the strength of evidence was rated low because of a lack of confirmatory RCT data.

## Clinical Event Outcomes, RCTs

No RCTs reported clinical event outcomes for comparisons of total n-3 FA versus placebo.

## Intermediate Outcomes, RCTs

Two RCTs that evaluated BP compared combined ALA and marine oil (ALA $1.2 \mathrm{~g} / \mathrm{d}$ [canola oil] or 2 g ["plant oil"] and 3.6 or 0.4 g EPA+DHA) versus placebo reported on intermediate outcomes. Neither trial found significant effects on BP, LDL-c, HDL-c, Tg, or Total:HDL-c ratio.

## Observational Studies, Intake

Seven studies evaluated total n-3 FA intake. For each outcome there was no consistent (and replicated) significant association between total n-3 FA intake and risk reduction. One of three studies found a significant association between higher total n-3 FA intake and higher risk of MACE. In contrast, one of three studies found an association of higher intake with reduced risk of CVD death; one of two studies found a significant association of higher intake with reduced risk of MI death; one study each found significant associations of higher intake with
lower risk of death from ischemic stroke or CHF. The other studies found no significant associations. No studies found significant associations with all-cause death (1 study), CHD death (2 studies), total (ischemic and hemorrhagic) stroke death (3 studies), total MI (1 study), total stroke (fatal and nonfatal) (1 study), SCD (1 study), or incident hypertension (1 study).

One study found no significant difference in association of total n-3 FA with total CVD death between men and women. Another study found no significant differences in association by different baseline Total:HDL-c ratios between total n-3 FA intake and risk of MI death, total stroke death, or ischemic stroke death.

## Observational Studies, Biomarkers

Three studies evaluated biomarkers for total n-3 FA (combined; plasma, blood, or erythrocyte). One study evaluated numerous outcomes and found significant associations between higher biomarker level and reduced risk of most outcomes (CVD death, CHD death, allcause death, CHD, ischemic stroke, SCD, AFib, and CHF), but not stroke death, total stroke, or hemorrhagic stroke. In contrast, a second study found no significant association with CHD. The third study found no significant association overall with incident hypertension, but did find a significant association in between higher total n-3 FA biomarker levels and lower risk of hypertension in younger women ( $<55$ years old) but not in older women.

## Marine Oil, Total: EPA+DHA $\pm D P A$

Overall, there is low, moderate, or high strength of evidence of no effect (or association) of marine oils and most clinical CVD outcomes and BP, and high strength of evidence of significant effects of higher marine oil intake on lipoproteins and Tg. There is insufficient evidence for many outcomes of interest. Specifically, there is high strength of evidence of that marine oils statistically significantly lower Tg—possibly with greater effects with higher doses and in people with higher baseline Tg-and statistically significantly raise HDL-c and LDL-c by similar amounts. There is also high strength of evidence that marine oil significantly lowers Total:HDL-c ratio and low strength of evidence that marine oil significantly lowers risk of ischemic stroke (for which no RCTs confirmed the observational study finding). There is a high strength of evidence of no effect of marine oil on risk of MACE, all-cause death, SCD, revascularization, and BP , moderate strength of evidence of no effect of marine oil on risk of AFib, and low strength of evidence of no effect of marine oil on risk of CVD death, CHD death, total CHD, MI, CHF, total stroke, and hemorrhagic stroke. Strength of evidence was rated as low for CHD and hemorrhagic stroke due to a lack of confirmatory RCT data; and for CVD death, CHF, and total stroke because RCTs and observational studies yielded conflicting conclusions (RCTs found no effect, observational studies found statistically significant associations). Strength of evidence was rated low for CHD death primarily because RCTs and observational studies both yielded imprecise estimates suggesting no effect/association. For MI, the strength of evidence was rated low primarily because the summary effect size estimate was relatively strong (HR = 0.88), but the $95 \%$ CI only minimally crossed the significance threshold ( $95 \%$ CI 0.77 to 1.02); this scenario yielded low confidence that the conclusion would remain stable with future RCTs and subsequent greater statistical power. This issue was also pertinent for CVD death where summary HR $=0.92$ ( $95 \%$ CI 0.82 to 1.02).There is insufficient evidence for other outcomes.

Four RCTs explicitly evaluated (purified) EPA and/or DHA ethyl esters; all other trials explicitly or implicitly evaluated marine oil preparations. No study directly compared
formulations. The effects on clinical and intermediate outcomes found among the ethyl ester trials were all statistically or qualitatively similar to the effects found in other studies.

## Clinical Event Outcomes, RCTs

Regarding clinical event outcomes, 19 trials in populations at increased risk for CVD (3 RCTs) and CVD populations (17 RCTs) mostly found no significant effects of marine oil (EPA + DHA $\pm$ DPA) versus placebo on specific clinical event outcomes. Across RCTs, EPA+DHA doses ranged from 0.34 to $6 \mathrm{~g} / \mathrm{d}$ (median $0.866 \mathrm{~g} / \mathrm{d}$ ). Followup ranged from 1 to over 10 years (median 3.9 years).

Two of 17 trials found significantly lower risk of all-cause death with EPA+DHA (both $0.866 \mathrm{~g} / \mathrm{d}$; $\mathrm{HR}=0.79$ and 0.91 ), however, the meta-analyzed HR was nonsignificant at 0.97 ( $95 \%$ CI 0.92 to 1.03 ) with no differences across trials by marine oil dose, followup time, or population (CVD, at risk, healthy). Four trials also found no within-study subgroup differences in effect on death for multiple subgroup comparisons.

Ten RCTs reported on MACE, only two of which found significant reductions in outcome with $0.866 \mathrm{~g} / \mathrm{d}$ EPA+DHA at 3.9 year followup and with $1.8 \mathrm{~g} / \mathrm{d}$ EPA at 5 year followup (in an at-risk population, but not in a parallel CVD population). Meta-analysis of MACE found a no effect ( $\mathrm{HR}=0.96$; $95 \%$ CI 0.91 to 1.02 ) with no significant differences across studies by marine oil dose (range $0.4-2 \mathrm{~g} / \mathrm{d}$ ), followup time (range $1-5 \mathrm{y}$ ), or population category. Within-study subgroup analyses found a significant effect in women but not men in one trial, but no significant difference in effect between sexes in a second trial, and no differences between multiple subgroups in three trials.

None of the 11 trials that reported on total MI found a significant effect. Meta-analysis, however, found a nonsignificant effect size (HR=0.88; 95\% CI 0.77 to 1.02), with no significant differences across studies by marine oil dose, followup time, or population category. In one trial, no significant difference in effect was found based on cointervention with B vitamins.

Two of seven RCTs found significant effects of $0.866 \mathrm{~g} / \mathrm{d}$ marine oil (EPA+DHA) on risk of CVD death in populations of people with existing CVD. Meta-analysis found a nonsignificant effect size (HR=0.92; 95\% CI 0.82 to 1.02), with no significant differences across studies by marine oil dose, followup time, or population.

Nine RCTs all found no significant effect of EPA+DHA with SCD; by meta-analysis (with the EPA trial), summary HR=1.04 (95\% CI 0.92 to 1.17). Seven RCTs also found no significant effect of marine oils with total stroke; by meta-analysis, summary HR=0.98 (95\% CI 0.88 to 1.09 ).

Six RCTs evaluated angina pectoris, three stable angina, one hospitalization for angina, and three unstable angina. One trial found that $1.8 \mathrm{~g} / \mathrm{d}$ of purified EPA ethyl ester had an additive effect on statin to reduce unstable angina incidence after 5 years in people with dyslipidemia; however the five trials in people with existing CVD found no significant effects of 0.84 to $6 \mathrm{~g} / \mathrm{d}$ marine oils. The six RCTs evaluating CHF had a similar pattern. The one trial of $0.85 \mathrm{~g} / \mathrm{d}$ marine oil in people with multiple risk factors for CHF found a significant risk reduction in CHF hospitalization with n-3 FA supplementation, but the five studies in people with existing CVD found no significant effects of 0.84 to $6 \mathrm{~g} / \mathrm{d}$ marine oils.

All EPA+DHA RCTs that evaluated revascularization (6 trials), CHD death (4 trials), total stroke death (3 trials), AFib (3 trials), and CHF death (1 trial) found no significant effect of marine oils. One trial found an effect in participants with diabetes that was not seen in those
without diabetes, but no test of interaction was reported. Two trials compared effect of marine oils on AFib in multiple subgroups, finding no significant differences.

Four EPA+DHA RCTs found inconsistent effects on cardiac death, with effect sizes ranging from 0.45 to 1.45 . One trial found a statistically significant reduction in cardiac death with $0.866 \mathrm{~g} / \mathrm{d}$ EPA+DHA at 3.5 years ( $\mathrm{RR}=0.65$; 95\% CI 0.51 to 0.82 ); one trial found a statistically significant increase in cardiac death with a fish diet with EPA+DHA supplements ( $0.855 \mathrm{~g} / \mathrm{d}$ EPA+DHA; HR=1.45; 95\% CI 1.05 to 1.99 ), but no significant effect on cardiac death among people only given advice to increase fish intake (by $0.45 \mathrm{~g} / \mathrm{d}$ EPA+DHA) or in two other trials of 0.96 and $2.6 \mathrm{~g} / \mathrm{d}$ EPA+DHA. The trial that found increased risk with combined fish diet and EPA+DHA supplementation found no significant difference in effect between multiple sets of subgroups based on drug cointervention.

## Intermediate Outcomes, RCTs

Twenty-nine RCTs that compared EPA+DHA to placebo evaluated systolic BP, of which 28 also reported on diastolic BP. Ten RCTs were in healthy populations, 13 in those at risk for CVD, and six in those with CVD. All trials found no significant difference in BP across EPA+DHA doses of 0.30 to $6 \mathrm{~g} / \mathrm{d}$ and followup durations of 1 month to 6 years. By metaanalysis, no significant effects on systolic (summary net difference $=0.10 \mathrm{mmHg} ; 95 \% \mathrm{CI}-0.20$ to 0.40 ) or diastolic (summary net difference $=-0.19 \mathrm{mmHg} ; 95 \% \mathrm{CI}-0.43$ to 0.05 ) BP were found. Four of the trials also found no effect on MAP. By meta-regression, no differences in effect across studies were found by marine oil dose, followup duration or population. Three trials directly compared different EPA+DHA doses and found no differences in effect ( $1.7 \mathrm{vs} .0 .8 \mathrm{~g} / \mathrm{d}$; 1.8 vs. 0.9 or $0.45 \mathrm{~g} / \mathrm{d} ; 3.4 \mathrm{vs} .1 .7 \mathrm{~g} / \mathrm{d}$ ). One trial found no difference in effect between people with normal BP or prehypertension.

Numerous included RCTs compared the effect of marine oils and placebo (or equivalent) on blood lipids. Thirty-nine RCTs evaluated LDL-c and 34 evaluated HDL-c. Marine oil doses ranged from 0.3 to $6 \mathrm{~g} / \mathrm{d}$ (median $2.4 \mathrm{~g} / \mathrm{d}$ ) and study followup times ranged from 1 month to 6 years (median 3 months). Meta-analysis of the effect of marine oils on LDL-c found a statistically significant, but small effect increasing LDL-c ( $1.98 \mathrm{mg} / \mathrm{dL}$; 95\% CI 0.38 to 3.58 ). Marine oils increased HDL-c also by a statistically significant, but small effect ( $0.92 \mathrm{mg} / \mathrm{dL}$; $95 \%$ CI 0.18 to 1.66). For both lipoprotein fractions, no significant differences in effect across studies were found by marine oil dose, followup duration or population. Seven studies found no significant differences in effect within study by EPA+DHA dose. For HDL-c, three trials found no significant difference in effect between people using statins or not; one or two trials, each, found no significant differences between subgroups based on sex or age. One trial found a larger HDL-c effect in a subgroup also randomized to an exercise regimen; one of two trials found a larger HDL-c effect in people with impaired glucose tolerance compared to those with normoglycemia. Eight trials mostly found no significant effects of marine oil ( $0.4-5 \mathrm{~g} / \mathrm{d}$ for 1 month to 3 years) on Total:HDL-c ratio, but with a statistically significant summary effect of -0.17 ( $95 \%$ CI -0.26 to -0.09 ). One trial of $2.8 \mathrm{~g} / \mathrm{d}$ EPA+DHA found no significant effect on LDL:HDL-c ratio; another trial found no significant difference in change in ratio between 3.4 and $1.7 \mathrm{~g} / \mathrm{d}$ EPA+DHA.

Forty-one included RCTs mostly found significant effects of marine oils $(0.3-6 \mathrm{~g} / \mathrm{d}$; median $2.4 \mathrm{~g} / \mathrm{d}$ for 1 month to 6 years; median 3 months) on Tg levels. Meta-analysis found a summary net change of $-24 \mathrm{mg} / \mathrm{dL}(95 \%$ CI -31 to -18$)$, with no significant difference in effect based on population or followup time across studies. By metaregression, each increase in mean
baseline Tg concentration by $1 \mathrm{mg} / \mathrm{dL}$ was associated with a greater net decrease in Tg concentration of $-0.15 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.22$ to -0.08 ; $\mathrm{P}<0.0001$ ); each increase of EPA+DHA dose by $1 \mathrm{~g} / \mathrm{d}$ was also associated with a greater net decrease in Tg concentration of $-5.9 \mathrm{mg} / \mathrm{dL}$ ( $95 \%$ CI -9.9 to $-2.0 ; \mathrm{P}=0.003$ ). No clear inflection point was found at any dose. Five of six trials found no significant difference in Tg change by EPA+DHA dose, but across trials all doses of 3.4 and $4 \mathrm{~g} / \mathrm{d}$ lowered Tg concentration by at least $30 \mathrm{mg} / \mathrm{dL}$ more than lower doses ( $1-2 \mathrm{~g} / \mathrm{d}$ ), while all pairwise comparisons of lower doses ( $1.7-3 \mathrm{~g} / \mathrm{d}$ ) to even lower doses ( $0.7-2.25 \mathrm{~g} / \mathrm{d}$ ) found much smaller differences between doses ( -17 to $6 \mathrm{mg} / \mathrm{dL}$ ). Two trials both found significantly larger Tg concentration lowering effects of EPA ( 3.6 or $3.3 \mathrm{~g} / \mathrm{d}$ ) than DHA ( 3.8 or $3.7 \mathrm{~g} / \mathrm{d}$ ). No significant differences were found based on statin use ( 4 trials), vitamin C use ( 1 trial), concurrent high or low linoleic acid diet (1 trial), concurrent general dietary advice (1 trial), or age (1 trial). One trial found a significantly larger effect on Tg among people also taking a multivitamin. One trial found a larger effect of higher dose EPA+DHA ( $1.8 \mathrm{~g} / \mathrm{d}$ ) in men than women, but no significant difference between sexes at $0.8 \mathrm{~g} / \mathrm{d}$. One trial found no significant difference in effect between people with impaired glucose tolerance and those with noninsulin dependent diabetes, but among those with diabetes, a larger effect was found in those with baseline HDL-c $\leq 35 \mathrm{mg} / \mathrm{dL}$ compared to higher levels.

## Observational Studies, Intake

Twenty-one observational studies evaluated associations between total EPA + DHA $\pm$ DPA intake (regardless of source) and numerous clinical outcomes. Only eight (38\%) of these found significant associations with any clinical outcome.

By meta-analysis, overall there is a statistically significant association between marine oil intake and CVD death across a median dose range of 0.066 to $1.58 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=$ 0.88 ; $95 \%$ CI 0.82 to 0.95 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1 ). This implies the possibility of a ceiling effect (where intake above a certain level adds no further benefit). However, at no dose threshold was there a statistically significant difference between the ES below the dose threshold (knot) and above the threshold. The best fit curve was found with a knot at $0.3 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at $0.2 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.26)$.

By meta-analysis, overall there no significant association between marine oil intake and CHD death across a median dose range of 0.04 to $2.1 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=1.09$; $95 \%$ CI 0.76 to 1.57). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) found stronger associations (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1) for knots below $0.7 \mathrm{~g} / \mathrm{d}$, but stronger associations at higher doses above $0.7 \mathrm{~g} / \mathrm{d}$. However, the differences in effect size between lower and higher doses were always highly nonsignificant, implying no difference in association. The best fit curve was found with a knot at $0.5 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at the lowest tested threshold, 0.1 $\mathrm{g} / \mathrm{d}(\mathrm{P}=0.46)$.

By meta-analysis, overall there no significant association between marine oil intake and all-cause death across a median dose range of 0.066 to $1.58 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.62$; $95 \%$ CI 0.31 to 1.25 ). However, meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) consistently found stronger associations (of higher dose
being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1). This implies the possibility of a ceiling effect (where intake above a certain level adds no further benefit). For thresholds $\leq 0.4 \mathrm{~g} / \mathrm{d}$ the associations are statistically significant at lower doses, but not statistically significant at higher doses. The difference between low- and high-dose associations is statistically significantly different at a threshold of $0.2 \mathrm{~g} / \mathrm{d}$ ( $\mathrm{P}=0.047$ ). The best fit curve was found with a knot at $0.3 \mathrm{~g} / \mathrm{d}$. This analysis may suggest that marine oil intake above about 0.2 to $0.4 \mathrm{~g} / \mathrm{d}$ may not further strengthen any association between higher marine oil intake and lower rate of all-cause death.

By meta-analysis, overall there no significant association between marine oil intake and CHD across a median dose range of 0.038 to $3.47 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.94$; $95 \% \mathrm{CI} 0.81$ to 1.10). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.4 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1, ES above know about 1). At all knot points the differences were nonsignificant. This weakly suggests the possibility of a ceiling effect (where intake above a certain level adds no further benefit). The best fit curve was found with a knot at $0.4 \mathrm{~g} / \mathrm{d}$. The P values for differences between lower- and higher-dose knots were between 0.12 and 0.14 at all knots $\geq 0.3 \mathrm{~g} / \mathrm{d}$.

By meta-analysis, overall there is a statistically significant association between marine oil intake and total stroke across a median dosage range of 0.025 to $0.6 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=$ 0.68 ; $95 \%$ CI 0.53 to 0.87 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found a much stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below know less than 1; ES above know greater than 1); although, the difference in effect sizes above and below the knots were never statistically significant This implies a possible ceiling effect ceiling effect (where intake above a certain level adds no further benefit). However, given that the differences between lower and higher dose ES remained large across the range of testable dose thresholds, the actual ceiling dose threshold may be above the analyzable range (i.e., $>0.5 \mathrm{~g} / \mathrm{d}$ ). The best fit curve was found with the lowest knot at $0.1 \mathrm{~g} / \mathrm{d}$. The P values for differences between lower- and higher-dose effect sizes ranged from 0.14 to 0.20 .

By meta-analysis, overall there is a statistically significant association between higher marine oil intake and lower risk of ischemic stroke across a median dosage range of 0.025 to 0.6 $\mathrm{g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.51$; $95 \%$ CI 0.29 to 0.89 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found a much stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot near or greater than 1). All effect sizes below the knots were statistically significant and all above the knots were nonsignificant. The differences between lower- and higher-dose effect sizes were all statistically significant ( $\mathrm{P}=0.03-0.049$ ). This implies a ceiling effect (where intake above a certain level adds no further benefit). However, it is unclear what the threshold may be, as it may be greater than the highest threshold tested (0.4 $\mathrm{g} / \mathrm{d})$. The best fit curve was found with a knot at either 0.3 or $0.4 \mathrm{~g} / \mathrm{d}$. The difference between lower-dose and higher-dose ES estimates was statistically significant with a knot at $0.1 \mathrm{~g} / \mathrm{d}$.

By meta-analysis, overall there is no significant association between marine oil intake and hemorrhagic stroke across a median dosage range of 0.025 to $0.6 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=$ $0.61 ; 95 \%$ CI 0.34 to 1.11 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found similar associations above and below the knots. At no threshold was the difference in effect sizes statistically significant. The best fit
curve was found with a knot at $0.1 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at $0.5 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.78)$.

By meta-analysis, overall there is a just-significant association between higher marine oil intake and decreased risk of CHF across a median dosage range of 0.014 to $0.71 \mathrm{~g} / \mathrm{d}$ (effect size per $g / d=0.76 ; 95 \%$ CI 0.58 to 1.00 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1 ). This implies the possibility of a ceiling effect (where intake above a certain level adds no further benefit). However, given that the differences between lower and higher dose ES remained large across the range of testable dose thresholds, the actual ceiling dose threshold may be above the analyzable range (i.e., $>0.5 \mathrm{~g} / \mathrm{d}$ ). At thresholds of 0.1 and $0.2 \mathrm{~g} / \mathrm{d}$, the difference in effect size at lower and higher doses were statistically significant ( P values 0.04 and 0.03 , respectively). But the most significant difference was found at the highest threshold tested, $0.5 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.02)$. The best fit curve was found with the lowest knot tested, 0.1 g/d.

A minority of studies found significant associations of decreased risk of other outcomes with increasing intake of EPA + DHA $\pm$ DPA: MACE (1 of 2 studies), all-cause death (1 of 3 studies), CVD death (1 of 4 studies), CHD death (3 of 7 studies), MI (1 of 2 studies), incident CHF ( 1 of 5 studies), and AFib (1 of 3 studies). No studies found significant associations with cardiac death (1 study), total stroke death (1 study), ischemic stroke death (1 study), coronary revascularization (1 study), ventricular arrhythmia (1 study), SCD (2 studies), and incident hypertension (1 study). One study each analyzed MI death and ischemic stroke death and found a significant association.

## Observational Studies, Biomarkers

Five studies evaluated combined EPA+DHA $\pm$ DPA biomarkers, including adipose tissue, cholesteryl ester, erythrocyte, phospholipid, and plasma n-3 FA levels. Of the outcomes evaluated, none was analyzed by more than two studies. One study each found no significant association between various biomarker levels and MI, hemorrhagic stroke, total stroke (with a P value of 0.07), or cardiac death. One study found a significant association between higher phospholipid EPA+DHA+DPA and incident CHD. Another found a significant association between higher adipose EPA+DHA+DPA and acute coronary syndrome in men, but not in women. Two studies each evaluated CHF, ischemic stroke, and MACE. For each outcome only one of the studies found significant associations with EPA + DHA $\pm$ DPA biomarker levels. In one of the studies of CHF, phospholipid EPA+DHA+DPA level was associated with the outcome in women only but cholesteryl ester EPA+DHA+DPA levels were not associated in either sex.

## EPA

For the most part, there is insufficient evidence regarding the effect of or association with EPA (specifically) and CVD clinical and intermediate outcomes. There is low strength of evidence of no association between EPA intake and CHD and between EPA biomarkers and AFib; no RCTs evaluated these outcomes.

## Clinical Event Outcomes, RCTs

Regarding clinical event outcomes, one trial in an at risk population (dyslipidemia), found that after 5 years, compared with placebo, people taking purified EPA $1.8 \mathrm{~g} / \mathrm{d}$ had
significantly lower risk of MACE and angina, but no significant difference in all-cause death, CHD death, coronary revascularization, SCD, or MI (also in the subgroup of people with prior CVD). Subgroup analysis for CHD death found no clear difference between those who also had CVD versus those without CVD.

## Intermediate Outcomes, RCTs

Two RCTs evaluated BP or lipid outcomes. One trial of purified EPA $3.8 \mathrm{~g} / \mathrm{d}$ versus placebo found no significant effect of EPA supplementation on systolic BP, diastolic BP, or MAP. This trial and another of EPA $3.3 \mathrm{~g} / \mathrm{d}$ found no significant effect of EPA supplementation on LDL-c or HDL-c. Both trials, however, found significant net reductions in Tg concentration ( -42 and $-23 \mathrm{mg} / \mathrm{dL}$ ). The trial of EPA $3.8 \mathrm{~g} / \mathrm{d}$ also found a significant reduction in Total:HDL-c ratio $(-0.2)$.

## Observational Studies, Intake

Eight studies evaluated associations between estimated total EPA intake and clinical outcomes. No outcome was evaluated by more than two studies. One study each found no significant association between EPA intake and acute coronary syndrome, ischemic stroke, or total stroke death. One study found a significant association between higher EPA intake and lower ischemic stroke death in healthy adults (in quantiles with median EPA intake $>0.07 \mathrm{~g} / \mathrm{d}$ in men and $>0.06 \mathrm{~g} / \mathrm{d}$ in women), but no association with hemorrhagic stroke death. One study found a significant association between higher EPA intake and lower risk of all-cause death ( $>0.01 \mathrm{~g} / \mathrm{d}$ ) in healthy adults; another study found a significant association with lower risk of MACE in healthy adults ( $>0.09 \mathrm{~g} / \mathrm{d}$ ). Two studies, each, found no significant associations between EPA intake and incident CHD (although P=0.06 in one) or CHD death. For both incident hypertension and CVD death, one of two studies found significant associations between higher EPA ( $0.02 \mathrm{~g} / \mathrm{d}$ for hypertension and $0.01 \mathrm{~g} / \mathrm{d}$ for CVD death) intake and lower risk of hypertension and CVD death; the other studies found no such associations.

## Observational Studies, Biomarkers

Ten studies evaluated associations between various EPA biomarkers and clinical outcomes. Three studies of healthy adults evaluated incident CHD. Two of these studies found that increased plasma or phospholipid EPA levels were associated with reduced risk of CHD; the third study found no significant association between blood EPA levels and CHD risk. Three studies (two in healthy adults, one in people with hypercholesterolemia) evaluated MACE; the study of people with hypercholesterolemia found an association of reduced MACE risk with higher plasma EPA, as did one study of phospholipid EPA in healthy adults. The third study found no significant association between erythrocyte EPA and MACE in healthy adults. Three studies, two in healthy adults and one in adults with a history of MI, evaluated CHF; in one study of healthy adults, higher plasma EPA was associated with reduced CHF risk, but the other study of healthy adults found no association with phospholipid or cholesteryl ester EPA and CHF risk. The study in people with a history of MI also found an association between higher blood EPA level and lower CHF risk. In this latter study, significant interactions were found for sex (no association was seen in women, in contrast with a significant association in men), statin use (those on statins had no association, in contrast with those not on statins), and baseline HDL-c level (those with higher HDL-c, $\geq 40 \mathrm{mg} / \mathrm{dL}$, had no association, in contrast with those with lower HDL-c, $<40 \mathrm{mg} / \mathrm{dL}$ ). No interactions were found for age, use of angiotensin receptor
blocker drugs, use of beta blocker drugs, diabetes, dyslipidemia, baseline LDL-c, hypertension, glomerular filtration function, or hypertriglyceridemia.

One of three studies found a significant association between higher EPA biomarkers (plasma EPA) and lower risk of death in healthy adults, but a second study of plasma EPA in healthy adults found no such association; nor did a study of blood EPA in people with a history of MI. One of two studies of plasma EPA in healthy adults found a significant association of higher plasma EPA with lower risk of CVD death. Two studies found no significant association between EPA biomarkers and ischemic stroke. One study found a significant association between erythrocyte EPA and incident hypertension. One study each found no associations between EPA biomarker levels and acute coronary syndrome, AFib, SCD, MI, hemorrhagic stroke, total stroke, cardiac death, CHD death, or total stroke death.

## DHA

For the most part, there is insufficient evidence regarding the effect of or association with DHA and CVD clinical and intermediate outcomes. There is moderate strength of evidence of no effect of purified DHA supplementation on BP or LDL-c and low strength of evidence of no association between DHA intake and incident CHD (from observational studies only).

## Clinical Event Outcomes, RCTs

No trial that reported clinical event outcomes evaluated DHA alone.

## Intermediate Outcomes, RCTs

Two trials compared purified DHA ( 3.6 and $2 \mathrm{~g} / \mathrm{d}$ ) to placebo and found no significant effects on systolic or diastolic BP. One of the trials also found no significant effect on MAP. Three trials of DHA (3.7, 3.6, or $2 \mathrm{~g} / \mathrm{d}$ ) also found no significant effect compared to placebo on LDL-c or HDL-c. Two trials ( 3.7 and $3.6 \mathrm{~g} / \mathrm{d}$ ) reported on Tg concentration changes and both found significant net reductions compared to placebo with DHA supplementation ( -27 and -29 $\mathrm{mg} / \mathrm{dL}$ ). The trial of DHA $3.6 \mathrm{~g} / \mathrm{d}$ also found a significant reduction in Total:HDL-c ratio ( -0.3 ) compared to placebo.

## Observational Studies, Intake

Eight studies evaluated the association between estimated total DHA intake (specifically) and risk of clinical outcomes. No outcome was reported in more than two studies. Two studies found significant associations between higher DHA intake and lower risk of incident hypertension in healthy young adults (18-30 years old in one study; 39-54 year old women in a subgroup of one study), but not in an older subgroup (55-89 years old in one study). In the study of young adults, a significant association was found in quartiles with DHA intake $>0.06 \mathrm{~g} / \mathrm{d}$ compared to quartiles with lower intake. One of two studies of healthy adults found an association of lower CVD death with DHA intake $>0.15 \mathrm{~g} / \mathrm{d}$. Two studies each found no association with CHD death or incident CHD (in populations with a broad range of ages, from 20-69 to 45-84 years old). One study each found significant associations of higher DHA intake with increased incidence of MACE ( $>0.15 \mathrm{~g} / \mathrm{d}$ DHA), ischemic stroke death ( $>0.15 \mathrm{~g} / \mathrm{d}$ ), and allcause death ( $>0.02 \mathrm{~g} / \mathrm{d}$ ). In one study each, no associations were found with acute coronary syndrome, ischemic stroke, hemorrhagic stroke death, or total stroke death.

## Observational Studies, Biomarkers

Eleven studies evaluated various DHA biomarkers and their associations with clinical outcomes. Overall, a high proportion of observational studies found statistically significant associations between higher DHA biomarker levels and decreased risk of outcomes. Four studies evaluated MACE (with various definitions); two found significant associations between higher DHA biomarker levels (phospholipid and adipose DHA) and lower risk of MACE in healthy adults. The other two studies found no association, one in hypercholesterolemic adults on statins (plasma DHA) and one in healthy adults (erythrocyte DHA). Two of three studies in healthy adults found significant associations between higher plasma or phospholipid DHA and lower CHD risk; the third study, also in healthy adults, found no association with blood DHA. Three studies evaluated CHF. One found associations between higher cholesteryl ester and phospholipid DHA and lower risk of incident CHF in healthy women, but not healthy men (whether the associations were significantly different between women and men was not reported). One study found that overall, there was no significant association of CHF with blood DHA in adults with a history of MI, but that there were significant associations in subgroups of people, such that significant association between higher blood DHA and lower risk of CHF were found in a population with a history of MI not taking a statin ( P interaction with statin use $=$ 0.003 ), $\geq 65$ years old ( P interaction $=0.051$ ), with LDL-c $\geq 100 \mathrm{mg} / \mathrm{dL}$ ( P interaction $=0.068$ ), and with HDL-c $\leq 40 \mathrm{mg} / \mathrm{dL}$ (P interaction $=0.096$ ). Three studies also evaluated all-cause death, two of which found significantly lower risk of death with higher plasma DHA (healthy adults) and blood DHA (in people with a history of MI who were not taking statins); another study of healthy adults found no association with plasma DHA.

Two studies found nonsignificant associations between higher cholesteryl ester DHA ( $\mathrm{P}=0.07$ ), phospholipid DHA ( $\mathrm{P}=0.08$ ), and plasma DHA ( $\mathrm{P}=0.052$ ) and lower risk of ischemic stroke in healthy adults. One study of healthy adults found an association between higher plasma DHA and lower risk of CVD death (both studies evaluated plasma DHA). One study each found significant associations between higher DHA biomarker levels and lower incidence of AFib, SCD, and CHD death (all plasma DHA in healthy adults). One study found a significant association between higher adipose DHA and lower risk of acute coronary syndrome in healthy men, but not healthy women. Another study found a significant association between higher erythrocyte DHA and lower risk of incident hypertension in healthy women aged 39 to 54 years, but not in women older than 54 years. One study found no significant associations between plasma DHA and both total stroke and total stroke death in healthy adults. One study, each, found no significant associations with MI, hemorrhagic stroke, or cardiac death.

## DPA

Overall, there is insufficient evidence regarding effect of or association between DPA (specifically) and CVD clinical and intermediate outcomes. There is low strength of evidence of no association between DPA biomarker levels and risk of AFib (from observational studies only).

## RCTs

No eligible RCTs compared purified DPA formulations versus placebo.

## Observational Studies, Intake

Two observational studies evaluated estimated total DPA intake (specifically). One study found no significant association between DPA intake and acute coronary syndrome in either healthy men or women. The other found significant associations between higher DPA intake and both incident CHD and MACE in healthy adults, in both instances with a significant association in the quartile with DPA intake $>0.04 \mathrm{~g} / \mathrm{d}$.

## Observational Studies, Biomarkers

Seven studies evaluated the association of various DPA biomarkers with clinical outcomes, all in healthy adults. No outcome was evaluated by more than three studies. One study in adults age $\geq 65$ years evaluated several clinical outcomes. It found significant associations between higher plasma DPA and lower risks of all-cause and CVD death, nonsignificant associations with incident CHF ( $\mathrm{P}=0.057$ ) and total stroke death ( $\mathrm{P}=0.056$ ), but no significant associations with AFib, SCD, hemorrhagic, ischemic, or total stroke, or CHD death. For both CHD and MACE, one study found a significant association between higher blood DPA and lower incident CHD, but two studies found no association with plasma or phospholipid DPA. Similarly, one study found a significant association between higher adipose tissue DPA and lower MACE risk, but two found no association with phospholipid or erythrocyte DPA. One study evaluated acute coronary syndrome and found a significantly lower risk in men with higher adipose tissue DPA, but no significant association in women. One study evaluated incident hypertension and found a significant association of higher erythrocyte DPA and lower hypertension risk in younger women (39-54 years old), but not older women ( $55-89$ years old). One study found no significant association with cardiac death.

## SDA

Overall, there is insufficient evidence regarding effect of or association between SDA (specifically) and CVD clinical and intermediate outcomes.

## RCTs

A single study compared $1.2 \mathrm{~g} / \mathrm{d}$ SDA to placebo in patients at risk for CVD and found no significant differences in change in systolic or diastolic BP, or LDL-c, HDL-c, or Tg at 6 weeks.

## Observational Studies

A single eligible observational study in healthy men evaluated baseline erythrocyte SDA and clinical outcomes. Erythrocyte SDA was not significantly associated with either MACE or cardiac death.

## Marine Oil FA Comparisons

There is insufficient evidence regarding comparisons of specific marine oil FA (e.g., EPA vs. DHA).

## Clinical Event Outcomes, RCTs

No trial that reported clinical event outcomes compared marine oil FA.

## Intermediate Outcomes, RCTs

Two trials that compared marine oil FA (EPA $3.8 \mathrm{~g} / \mathrm{d}$ vs. DHA $3.6 \mathrm{~g} / \mathrm{d}$; EPA+DHA 3.4 and $1.7 \mathrm{~g} / \mathrm{d}$ vs. EPA $1.8 \mathrm{~g} / \mathrm{d}$ ) found no significant differences in effect on BP, LDL-c, HDL-c, Tg, or Total:HDL-c ratio.

One trial compared $2.0 \mathrm{~g} / \mathrm{d}$ SDA and $1.9 \mathrm{~g} / \mathrm{d}$ EPA+DHA+DPA in healthy people. At 2 month followup, no significant differences in change in systolic or diastolic BP, or LDL-c, HDLc, Tg, Total:HDL-c, or LDL:HDL-c ratios were found.

#### Abstract

ALA There is moderate strength of evidence of no significant effect of ALA intake on BP, LDL-c, HDL-c, or Tg. There is low strength of evidence of no association between ALA intake or biomarker level and CHD or CHD death, AFib, and CHF, each based primarily on observational studies; there was only a single or no RCTs evaluating these outcomes. There is insufficient evidence regarding other outcomes.

## Clinical Event Outcomes, RCTs

Two RCTs that evaluated ALA supplementation versus placebo reported clinical event outcomes, one in participants with CVD and one in healthy participants. All analyses were nonsignificant, for all-cause death (2 trials) and from one trial each, MACE, CVD death, cardiac death, CHD death, CHF death, total MI, incident angina, total stroke, ventricular arrhythmia, and SCD. Within-study subgroup analyses revealed no significant differences in effect for various subgroups for MACE (1 trial) or with or without diabetes for CHD death (1 trial).

## Intermediate Outcomes, RCTs

Five ALA RCTs evaluated BP, with doses ranging from 1.4 to $5.9 \mathrm{~g} / \mathrm{d}$ for 1 to 3.4 years. All found no significant effect on systolic or diastolic BP, mostly with wide confidence intervals. One of the trials found no significant difference in effect of ALA on BP between a subgroup with hypertension and the study population as a whole. Another trial found no significant difference in effect between 1.4 and $5.9 \mathrm{~g} / \mathrm{d}$ ALA. No trial reported on MAP.

Five trials reported no significant effects of ALA on LDL-c, HDL-c, Tg, or Total:HDL-c ratio (3 trials). No differences in effect were found in the one trial that compared 1.4 and $5.9 \mathrm{~g} / \mathrm{d}$ ALA. No trial reported on LDL:HDL-c ratio.

## Observational Studies, Intake

Thirteen observational studies evaluated ALA intake. One of these was a pooling of 11 prior studies (the pooled studies were not included in duplicate for the outcomes evaluated by the pooling study). The large majority of analyses found no significant associations; only two studies found any significant associations between higher ALA intake and clinical outcomes.

By meta-analysis, overall there is no statistically significant association between ALA intake and CHD death across a median dose range of 0.59 to $2.5 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.94$; $95 \%$ CI 0.85 to 1.03). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.6 to $1.2 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at higher doses than at lower doses (ES above knot < ES below knot); although the differences were generally small and all were nonsignificant. The best fit curve was found with a knot at $0.9 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at $1.2 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.44)$, the highest dose threshold that could be tested.

By meta-analysis, overall there is no association between ALA intake and CHD across a median dosage range of 0.2 to $2.5 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.97 ; 95 \%$ CI 0.92 to 1.03). Metaanalyses with the addition of a spline knot point at different dose thresholds (from 0.5 to $1.4 \mathrm{~g} / \mathrm{d}$ ) consistently found marginally smaller ES at lower doses than at higher doses. At no dose threshold was there a statistically significant difference between the ES below the dose threshold (knot) and above the threshold. The best fit curve was found with a knot at $0.7 \mathrm{~g} / \mathrm{d}$, the threshold that also had the lowest P value ( $\mathrm{P}=0.34$ ).

Two studies both found significant associations between higher ALA intake and reduced all-cause death (>2.2 g/d in healthy adults; also in healthy men but insufficient data were reported regarding a dose threshold). One of two studies found a significant association between higher ALA intake ( $>0.6 \mathrm{~g} / \mathrm{d}$ ) and lower risk of SCD in healthy women but not in a subset of women with CVD; the second study found no significant association in healthy adults. One of two studies found a significant association between higher ALA intake (unclear threshold) and lower risk of CVD death in younger men (35-57 years old), but another study found no association in older men ( $\geq 65$ years old). For all other analyzed clinical outcomes, no significant associations were found with ALA intake, including CHF (4 studies), CVD (3 studies), MACE (2 studies), hemorrhagic and ischemic stroke (2 studies each), AFib (1 study), and hypertension (1 study).

## Observational Studies, Biomarkers

Eight studies evaluated various ALA biomarkers. Almost all analyses found no significant associations between ALA biomarkers and clinical outcomes. No outcome was evaluated by more than three studies. For CHF, one study found a significant association between higher plasma ALA and CHF in healthy men, but two other studies found no significant associations in healthy adults across levels of plasma, cholesteryl ester, or phospholipid ALA. One of two studies found a significant association between higher plasma ALA and lower risk of CVD death, but the other study found no significant association with plasma ALA in healthy adults. No significant associations were found for ischemic stroke (3 studies), incident CHD, hemorrhagic and total stroke (2 studies each), MACE (2 studies), all-cause death (2 studies), or AFib, SCD, incident hypertension, cardiac death, or CHD death (1 study each).

## Marine Oil Versus ALA

There is insufficient evidence of direct comparisons between marine oil and ALA intake on CVD outcomes. Across studies, the indirect comparison between marine oil and ALA is unclear, largely because there are insufficient studies that evaluated ALA. However, for Tg and HDL-c, where there is high strength of evidence of significant effects of higher dose of marine oil improving Tg and HDL-c, there is moderate strength of evidence of no effect of ALA intake on these intermediate outcomes.

## Clinical Event Outcomes, RCTs

No trial that reported clinical event outcomes directly compared marine oils and ALA.

## Intermediate Outcomes, RCTs

One trial that compared two doses of EPA+DHA ( 1.7 and $0.8 \mathrm{~g} / \mathrm{d}$ ) with ALA $4.5 \mathrm{~g} / \mathrm{d}$ found no differences in systolic or diastolic BP at 4 months. Across trials, there was no evidence
that intake of any type of n-3 FA had an effect on BP; no difference in effect was apparent between marine oil and ALA trials.

Two trials that compared EPA+DHA ( 0.8 and $1.7 \mathrm{~g} / \mathrm{d}$ in one trial, $0.4 \mathrm{~g} / \mathrm{d}$ in the other) to ALA ( $4.5 \mathrm{~g} / \mathrm{d}$ [rapeseed oil margarine] and $2 \mathrm{~g} / \mathrm{d}$ ["plant oil" margarine], respectively) for 6 months and 3.4 years found no differences between intake of n-3 FA and LDL-c, HDL-c, or Tg levels. Neither trial reported on lipid ratios. No evident differences were found across trials between marine oils and ALA for their (nonsignificant) effects on LDL-c and HDL-c. In contrast with the two trials that directly compared EPA+DHA and ALA, 32 marine oil (versus placebo) trials fairly consistently found significant effect on Tg reduction in contrast with the four ALA (versus placebo) trials, which mostly had imprecise estimates of effects on Tg.

## Subgroup Analyses Summary

Overall, 24 RCTs and 9 observational studies reported on subgroup (or factorial) analyses. For most outcomes, there is insufficient evidence regarding differential effects (or associations) in different subgroups of study participants evaluated within studies. Metaregression results across studies are summarized in the summary by n-3 FA, above. (In brief, only for the effect of marine oil on Tg was there an indication across studies of interactions by dose and baseline Tg, with larger effects with higher dose and higher baseline Tg.) Among outcomes with sufficient RCT data to allow meta-analysis, no discernable difference in effect was found across trials based on publication year.

Twenty-two subgroup analyses by sex were reported ( 10 with ALA, 11 with marine oil, 1 with total n-3 FA). One of three RCTs of marine oil on MACE found a greater beneficial effect of n-3 FA in women (HR [supplement vs. placebo] $=0.82$ in women vs. 1.04 in men; P interaction $=0.04$ ). One of three observational studies of CHF found a stronger association with between higher blood EPA and lower risk of CHF in men than women (HR [lower intake vs. higher intake] = 5.82 in men vs. 0.69 in women; P interaction $=0.008$ ), but no interaction with blood DHA. One RCT found a stronger effect on lowering Tg of supplementation with higherdose marine oil ( $1.8 \mathrm{~g} / \mathrm{d}$ ) in men than in women (difference not reported; P interaction $=0.038$ ), but this interaction was not found with lower-dose marine oil ( $0.7 \mathrm{~g} / \mathrm{d}$ ). All 19 other analyses were not statistically significant (or no statistical difference was reported).

Twenty subgroup analyses by statin use were reported (1 with ALA, 19 with marine oil). All but one study found difference in effect or association based on statin use. One study found a stronger association between higher blood DHA and, separately, higher blood EPA, and lower risk of CHF in those not using statins; DHA: HR [lower intake vs. higher intake] = 6.65 (without statins) vs. 0.74 (with statins), P interaction = 0.003; EPA: HR [lower intake vs. higher intake] = 6.40 (without statins) vs. 1.45 (with statins), P interaction $=0.048$. A relatively small number of RCTs of lipoproteins (LDL-c and HDL-c) and Tg analyzed interactions between n-3 FA and statins and found no interaction between statin use and the effect of marine oil supplementation on lipids (LDL-c 5 RCTs, Tg 4 RCTs, HDL-c 3 RCTs). No studies explicitly compared the interaction of n-3 FA intake (or biomarker level) with aspirin intake on outcomes.

Sixteen subgroup analyses comparing those with and without diabetes were reported (6 with ALA, 10 with marine oil). Two RCT analyses reported only that a statistically significant effect of n-3 FA was found among participants with diabetes but no significant effect was found those without diabetes (marine oil and CHD death, ALA and ventricular arrhythmia). All other analyses reported no difference in effect or association based on diabetes status.

## Adverse Events

Of 61 RCTs included in this systematic review, only 4 RCTs of EPA/DHA ethyl ester, 19 RCTs of marine oils (EPA+DHA), 1 RCT of ALA, and 1 RCT comparing total n-3 FA, marine oil, ALA, and placebo reported information on adverse events that may or may not be associated with the interventions. There were no serious adverse events that were considered related to the study interventions in these 25 RCTs. Four of the 20 marine oil RCTs and one of the two ALA trials reported no adverse events. Most of the reported adverse events were mild and transient, such as gastrointestinal discomforts, nausea, skin abnormalities, eczema, pain, allergic reactions, fishy taste, headache, and infection. The most common adverse events related to n-3 FA supplements (that occurred more frequently among those taking supplements) were mild gastrointestinal effects such as belching (0.4-58\% [marine oil] vs. 1.7-4\% [placebo]; 2 studies), nausea ( $3.6-8.9 \%$ vs. $1.0-5.6 \%$, 2 studies), diarrhea ( $5.1-8.9 \%$ vs. $2.0 \%$, 1 study), or fishy taste ( $5.3-67 \%$ vs. $0-3 \%, 2$ studies), or combined gastrointestinal symptoms (e.g., nausea, diarrhea, or epigastric discomfort) (marine oil: $1.5 .0-6 \%$ vs. $0.8-4.5 \%, 7$ studies; total n-3 FA: $1.3 \%$ vs. $0.8 \%$, 1 study; ALA: $0.8 \%$ vs. $0.8 \%$ ). Only one study explicitly reported on bleeding (hemorrhages such as cerebral and fundal bleedings, epistaxis, and subcutaneous bleeding), finding a higher rate with EPA ethyl ester and statin (1.1\%) versus statin alone ( $0.6 \%, \mathrm{P}<0.0001$ ). This study was one of only two trials that reported statistically significantly more adverse events with marine oils than placebo. No study reported statistically significant higher rates of serious or severe adverse events between study arms, and no serious or severe adverse event was attributed to n-3 FA. Six of the marine oil trials explicit stated that most or all adverse events were mild. Three studies reported on the rate of adverse events leading to discontinuation, none of which were reported as statistically significantly different between groups (1.4-17\% vs. 0.9-26\%).

## Summary by Key Question

## Key Question 1

What is the efficacy or association of n-3 FA (EPA, DHA, EPA $+D H A, D P A, S D A, A L A$, or total n-3 FA) exposures in reducing CVD outcomes (incident CVD events, including all-cause death, CVD death, nonfatal CVD events, new diagnosis of CVD, peripheral vascular disease, CHF, major arrhythmias, and hypertension diagnosis) and specific CVD risk factors (BP, key plasma lipids)?

- Total n-3 FA
o Overall, there is insufficient evidence regarding the effect of or association between total n-3 FA (combined ALA and marine oils) and clinical or intermediate outcomes. There is low strength of evidence of no association between total n-3 FA intake and stroke death, and total (fatal and nonfatal) MI (each association based on longitudinal observational studies of dietary intake).
o For each outcome there was no consistent (and replicated) significant association between total n-3 FA intake and risk reduction.
- Marine oils
o There is high strength of evidence of that marine oils statistically significantly lower Tg —possibly with greater effects with higher doses and in people with higher baseline Tg-and statistically significantly raise HDL-c and LDL-c by similar amounts. There is also high strength of evidence that marine oil significantly lowers Total:HDL-c ratio.
o There is low strength of evidence that marine oil significantly lowers risk of ischemic stroke.
o There is a high strength of evidence of no effect of marine oil on risk of MACE, all-cause death, SCD, revascularization, and BP; moderate strength of evidence of no effect of marine oil on risk of AFib; and low strength of evidence of no effect of marine oil on risk of CVD death, CHD death, total CHD, MI, angina pectoris, CHF, total stroke, and hemorrhagic stroke. There is insufficient evidence for other outcomes.
- Marine oil, EPA
o There is insufficient evidence regarding the effect of or association with EPA (specifically) and most CVD clinical and intermediate outcomes. There is low strength of evidence of no association between EPA intake and CHD and between EPA biomarkers and AFib.
- Marine oil, DHA
o For the most part, there is insufficient evidence regarding the effect of or association with DHA and CVD clinical and intermediate outcomes. There is moderate strength of evidence of no effect of purified DHA supplementation on BP or LDL-c and low strength of evidence of no association between DHA intake and incident CHD (from observational studies).
- Marine oil, DPA
o Overall, there is insufficient evidence regarding effect of or association between DPA (specifically) and most CVD clinical and intermediate outcomes. There is low strength of evidence of no association between DPA biomarker levels and risk of AFib.
- SDA
o Overall, there is insufficient evidence regarding effect of or association between SDA (specifically) and CVD clinical and intermediate outcomes.
- ALA
o There is moderate strength of evidence of no significant effect of ALA intake on BP, LDL-c, HDL-c, or Tg. There is low strength of evidence of no association between ALA intake or biomarker level and CHD or CHD death, AFib, and CHF, each based on observational studies. There is insufficient evidence regarding other outcomes.

## Key Question 1, Subquestions

1.1.1. What is the efficacy or association of n-3 FA in preventing CVD outcomes in people without known CVD (primary prevention)?

- There was insufficient evidence for cardiac death, CHF death, ischemic stroke death, hemorrhagic stroke death, revascularization, acute coronary syndrome, angina pectoris, ventricular arrhythmia, incident hypertension, TC/HDL-c ratio, and LDL-c/HDL-c ratio.
- There was insufficient RCT evidence and inconsistent observational evidence for CHD death, MI death, all-cause death, total MI, and SCD.
- There was insufficient RCT evidence but observational evidence of no association for MACE, CVD death, total stroke death, incident CHD, total stroke, ischemic stroke, hemorrhagic stroke, AFib, and CHF.
- There was strong RCT evidence for no effect for BP (systolic and diastolic), MAP (only 3 trials), LDL-c, and HDL-c.
- There was strong RCT evidence for a significant protective effect for Tg .
1.1.2. What is the efficacy or association of n-3 FA in preventing CVD outcomes in people at high risk for CVD (primary prevention)?
- There was insufficient evidence for CVD death, cardiac death, CHD death, MI death, CHF death, total stroke death, ischemic stroke death, hemorrhagic stroke death, incident CHD, revascularization, acute coronary syndrome, angina pectoris, total stroke, ischemic stroke, hemorrhagic stroke, SCD, AFib, ventricular arrhythmia, CHF, incident hypertension and MAP.
- There was inconsistent RCT evidence for total MI.
- There was strong RCT evidence for no effect for MACE, all-cause death, BP (systolic and diastolic), LDL-c, HDL-c, TC/HDL-c ratio, and LDL-c/HDL-c ratio.
- There was strong RCT evidence for a significant protective effect for Tg .
1.1.3. What is the efficacy or association of n-3 FA in preventing CVD outcomes in people with known CVD (secondary prevention)?
- There was insufficient evidence for MI death, CHF death, total stroke death, ischemic stroke death, hemorrhagic stroke death, CHD, acute coronary syndrome, angina pectoris, ischemic stroke, hemorrhagic stroke, ventricular arrhythmia, incident hypertension, MAP, TC/HDL-c ratio, and LDL-c/HDL-c ratio.
- There was inconsistent RCT evidence for CVD death and cardiac death. There was RCT evidence of no effect for MACE, CHD death, all-cause death, total MI, revascularization, total stroke, SCD, AFib, and CHF.
- There was strong RCT evidence of no effect for BP (systolic and diastolic) and LDL-c.
- There was strong RCT evidence of a protective effect for HDL-c and Tg.
1.2. What is the relative efficacy of different n-3 FA on CVD outcomes and risk factors?
- There is low strength of evidence of no difference between EPA+DHA and its individual components.
- There is low strength of evidence of greater efficacy of marine oils over ALA.
1.3. Can the CVD outcomes be ordered by strength of intervention effect of $n-3$ FA ?
- Based on the summary effect sizes of meta-analyzed RCTs, marine oils had no significant effect on CVD outcomes. The order of effect sizes of CVD outcomes with sufficient data to allow meta-analysis, was MI (ES=0.88), CVD death ( $\mathrm{ES}=0.92$ ), MACE ( $\mathrm{ES}=0.96$ ), allcause death ( $\mathrm{ES}=0.97$ ), total stroke ( $\mathrm{ES}=0.98$ ), and SCD ( $\mathrm{ES}=1.04$ ).

## Key Question 2

n-3 FA variables and modifiers
2.1. How does the efficacy or association of n-3 FA in preventing CVD outcomes and with CVD risk factors differ in subpopulations, including men, premenopausal women, postmenopausal women, and different age or race/ethnicity groups?

- There was insufficient evidence to assess the efficacy or association of n-3 FA in preventing CVD outcomes and with CVD risk factors in subgroups based on race/ethnicity and whether women were pre- or postmenopausal.
- 5 studies (mostly observational) found no significant differences in association based on age, with cutoffs for subgroups ranging between 60 and 70 years of age.
- Two studies found no interaction with age as a continuous variable. One trial found a significant difference in favor of women, two observational studies found a significant difference in favor of men, and 9 studies (mix of RCT and observational) found no difference between men and women.
2.2 What are the effects of potential confounders or interacting factors-such as plasma lipids, body mass index, BP, diabetes, kidney disease, other nutrients or supplements, and drugs (e.g., statins, aspirin, diabetes drugs, hormone replacement therapy)?
- There was insufficient evidence to assess the following potential confounders or interacting factors: beta-blocker use, baseline HDL-c, glargine use, nitrate use, digoxin use, diuretic use, eGFR, ACEi use, anticoagulant use, total cholesterol levels, or use of fish oil supplements.
- There was inconsistent evidence for the following potential confounders or interacting factors: Tg levels, statin use, b-vitamin use, and baseline LDL-c.
- There was evidence of no interactions with body mass index, hypertension status, diabetes status, and baseline TC/HDL-c ratio.
2.3 What is the efficacy or association of different ratios of n-3 FA components in dietary supplements or biomarkers on CVD outcomes and risk factors?
- No study directly compared efficacy or association of different ratios of n-3 FA components on outcomes. Across studies, there were insufficient data to make these assessments.
2.4 How does the efficacy or association of n-3 FA on CVD outcomes and risk factors differ by ratios of different n-3 FA—DHA, EPA, and ALA, or other n-3 FA?
- No study directly compared efficacy or association of different ratios of n-3 FA components on outcomes. Across studies, there were insufficient data to make these assessments.
2.5 How does the efficacy or association of n-3 FA on CVD outcomes and risk factors differ by source (e.g., fish and vs. seafood, common plant oils (e.g., soybean vs,, canola), fish oil supplements, fungal-algal supplements, flaxseed oil supplements)?
- No study directly compared efficacy or association of different sources of n-3 FA on outcomes. Across studies, there were insufficient data to make these assessments.
2.6 How does the ratio of n-6 FA to n-3 FA intakes or biomarker concentrations affect the efficacy or association of n-3 FA on CVD outcomes and risk factors?
- No trial or observational studies evaluated n-6 FA to n-3 FA intake concentrations and no differences across studies by this ratio was evident.
2.7 Is there a threshold or dose-response relationship between n-3 FA exposures and CVD outcomes and risk factors? Does the study type affect these relationships?
- Among trials, for all clinical CVD outcomes there is insufficient evidence regarding a dose-response relationship within or between trials.
- For BP, LDL-c, and HDL-c, trials do not find significant differences in effect by marine oil dose either within or between trials.
- Trials comparing marine oil doses mostly found no significant difference between higher and lower dose marine oils. However, a possible pattern could be discerned such that higher doses of 3.4 or $4 \mathrm{~g} / \mathrm{d}$ reduced Tg by at least $30 \mathrm{mg} / \mathrm{dL}$ more than lower doses of 1 to $2 \mathrm{~g} / \mathrm{d}$. Higher doses $\leq 3 \mathrm{~g} / \mathrm{d}(1.7-3 \mathrm{~g} / \mathrm{d})$ yielded much smaller relative differences in Tg change compared to lower doses $(0.7-2.25 \mathrm{~g} / \mathrm{d})$. By metaregression, each increase of EPA + DHA dose by $1 \mathrm{~g} / \mathrm{d}$ was associated with a greater net change Tg of $-5.9 \mathrm{mg} / \mathrm{dL}$ ( $95 \%$ CI -9.9 to -2.0 ; $\mathrm{P}=0.003$ ); no inflection point was found above which the association plateaued.
- Metaregressions of observational studies yielded the following conclusions:

0 For all-cause death, there may be a ceiling effect at about $0.2 \mathrm{~g} / \mathrm{d}$, such that increasing marine oil intake up to this level may be associated with lower allcause death, but increasing intake above this level may not be associated with further decreased risk.
o For total stroke, ischemic stroke, and CHF, at lower ranges of intake there were statistically significant associations between higher marine oil intake level and lower risk of outcome, in contrast to associations found at higher ranges of intake. However, the associations at lower and higher doses were not statistically significant from each other. For ischemic stroke, associations between higher doses and risk of stroke were stronger and statistically significant across lower doses than at higher doses (with thresholds between lower and higher doses from 0.1 and $0.4 \mathrm{~g} / \mathrm{d}$ ) and the differences in associations between lower and higher doses were statistically significant. Any dose inflection point that may exist is likely to be beyond the range of testable thresholds (i.e., $>0.4 \mathrm{~g} / \mathrm{d}$ ). Similarly, for CHF significant associations were found at lower doses, in contrast to at higher doses, with thresholds ranging from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$, and the differences were statistically significant at most thresholds. Any dose inflection point that may exist is likely to be beyond the range of testable thresholds (i.e., $>0.5 \mathrm{~g} / \mathrm{d}$ ).
o For CVD death, CHD death, total CHD, and hemorrhagic stroke, there were no apparent differences in association between marine oil intake dose and outcome at lower or higher dose ranges.
o For CHD death and CHD, there were no apparent differences in association between ALA intake dose and outcome at lower or higher dose ranges.
2.8 How does the duration of intervention or exposure influence the effect of n-3 FA on CVD outcomes and risk factors?

- None of the meta-regressions found a significant interaction for follow-up time. No difference in effect was found within studies at different durations of intervention. Observational studies did not evaluate differences in duration of exposure.
2.9 What is the effect of baseline n-3 FA status (intake or biomarkers) on the efficacy of n-3 FA intake or supplementation on CVD outcomes and risk factors?
- No study found a significant difference in subgroups based on baseline fish or n-3 FA intake.

## Key Question 3

## Adverse events

3.1 What adverse effects are related to n-3 FA intake (in studies of CVD outcomes and risk factors)?

- No serious or severe adverse events were related to n-3 FA intake (supplementation). Most reported adverse events were mild and gastrointestinal in nature; however, only 2 of 25 trials reported statistically significant differences in adverse events between n-3 FA supplements and placebo.
3.2 What adverse events are reported specifically among people with CVD or diabetes (in studies of CVD outcomes and risk factors)?
- Among 10 trials of patients with CVD (9 with marine oil, 1 with total n-3 FA, 2 with ALA), either no adverse events or no significant difference between n-3 FA and placebo were reported.
- A single study reported adverse events from a trial of people with diabetes, finding no significant differences in serious or nonserious adverse events between marine oil and placebo.

## Discussion

## Overall Summary of Key Findings

In this systematic review we identified 61 eligible RCTs (in 82 publications) and 37 eligible prospective longitudinal studies (in 65 publications) for inclusion, based on prespecified eligibility criteria. Most of the RCTs evaluated the effects of marine oil supplements (EPA + DHA) compared with placebo on clinical CVD outcomes in populations at risk for CVD or with CVD, while most of the observational studies examined the associations between intake of various individual n-3 FA, alone and in combination with each other, in relation to long-term CVD events in generally healthy populations. The RCTs of intermediate CVD outcomes (BP and lipids) were conducted in all three populations of interest (generally healthy, at risk for CVDprimarily due to dyslipidemia, or with CVD). However, none of the observational studies evaluated BP or lipids.

The main findings of the studies, regarding effect or association of higher n-3 FA intake or biomarker level and outcomes are summarized in the following tables. Table A includes analyses of n-3 FA and outcome pairs for which there is evidence to support an effect or
association of higher n-3 FA intake and risk of a CVD outcome or on a CV risk factor. These include high strength of evidence that higher marine oil intake statistically significantly raises HDL-c, lowers Tg concentration and Total:HDL-c ratio, but also raises LDL-c. There is low strength of evidence that higher marine oil intake is associated with lower risk of ischemic stroke.

Table B includes analyses of n-3 FA and outcome pairs for which there is evidence supporting no effect or association of n-3 FA intake (or biomarker level) and outcomes. These include high strength of evidence for no effect of or association between marine oil intake and MACE, all-cause mortality, SCD, coronary revascularization, or BP; moderate strength of evidence of no association between marine oil intake and AFib, and between DHA intake and BP or LDL-c, and between ALA and BP, LDL-c, HDL-c, or Tg; and low strength of evidence of no association between total n-3 FA intake and stroke death or MI; between marine oil intake and CVD death, CHD death, total CHD, MI, angina pectoris, CHF, total stroke or hemorrhagic stroke; between EPA intake and CHD; between EPA biomarkers and AFib; between DHA intake and CHD; between DPA biomarkers and AFib; and between ALA intake and CHD, CHD death, AFib, or CHF. Analyses of n-3 FA and outcome pairs not included in the table provided insufficient evidence.

In brief, 61 RCTs and 37 longitudinal observational studies were included. Most RCTs and observational studies had few risk of bias concerns.

- Total n-3 FA (EPA+DHA+ALA):
o There is low strength of evidence of no association between total n-3 FA intake and stroke death or MI.
o There is insufficient evidence for other outcomes.
- Marine oils, total (primarily EPA+DHA):

0 There is high strength of evidence that higher marine oil intake lowers Tg , raises HDL-c, lowers Total:HDL-c ratio, but raises LDL-c; also moderate or high strength of evidence that higher marine oil intake does not affect MACE, allcause death, SCD, coronary revascularization, AFib, or BP.
o There is low strength of evidence of associations between higher marine oil intake and decreased risk of ischemic stroke. There is low strength of evidence of no association with CVD death, CHD death, total CHD, MI, angina pectoris, CHF, total stroke, or hemorrhagic stroke.
o There is insufficient evidence for other outcomes.

- Marine oil FA (EPA, DHA, DPA), individually:
o There is moderate strength of evidence of no effect of purified DHA supplementation (intake) and altering BP or LDL-c.
o There is low strength of evidence of no associations between EPA or DHA intake (separately) and CHD, and between EPA or DPA biomarkers and AFib.
o There is insufficient evidence for other specific marine oil FA (EPA, DHA, DPA, or SDA) and outcomes.
- ALA:
o There is moderate strength of evidence of no effect of ALA intake on BP, LDL-c, HDL-c, or Tg.
o There is low strength of evidence of no association between ALA intake or biomarker level and CHD, CHD death, AFib, and CHF.
o There is insufficient evidence for other outcomes.
- Other n-3 FA analyses:
o There is insufficient evidence comparing n-3 FA to each other.
- Subgroup analyses:
o 19 of 22 studies found no interaction of sex on any effect of n-3 FA.
o 19 of 20 studies found no differential effect by statin co-use.
o Within 16 studies evaluating diabetes subgroups, 2 found statistically significant beneficial effects of n-3 FA in those with diabetes, but not in those without diabetes, but no test of interaction was reported.

The 61 RCTs mostly compared marine oil supplements to placebo on CVD outcomes in populations at risk for CVD or with CVD, while the 37 observational studies mostly examined associations between various individual n-3 FA and long-term CVD events in generally healthy populations. Compared to the prior report on n-3 FA and CVD, there is more robust RCT evidence on ALA and on clinical CV outcomes; also, by design there are newly added data on associations between n-3 FA biomarkers and CV outcomes. However, conclusions regarding the effect of n-3 FA intake on CV outcomes or associations with outcomes remain substantially unchanged. Future RCTs would be needed to establish adequate evidence of the effect of n-3 FA on CVD outcomes or to clarify differential effects in different groups of people.

Studies within each category of analysis (by study design and by n-3 FA) were diverse, due to differences in outcomes evaluated, definitions of specific outcomes, as well as the n-3 FA intervention doses or compositions (for RCTs) or the dietary/biomarker n-3 FA exposure assessments and quantifications (for observational studies). Overall we found a lack of conclusive or consistent findings for CVD events within RCTs, mostly due to sparse data and underpowered trials as indicated by wide confidence intervals. The majority of the individual RCTs did not find statistically significant effects of marine oil supplements (EPA+DHA, various doses) on CVD outcomes. Pooled meta-analyses suggest that people with CVD or at risk for CVD who received marine oil supplements may have a small risk reduction in CVD death (pooled HR 0.92; 95\% CI 0.82 to 1.02) compared with those who received placebo. Across outcomes, the effects of marine oil supplements were often larger in earlier RCTs than in more recent RCTs. These data may be confounded by shifts over time in concomitant therapy to reduce CVD risk (e.g., statins, aspirin), decreasing smoking rates, and overall declining rates of CVD events. No meta-regression across studies found significant changes in effect sizes by publication year; however, it is likely that all such meta-regressions of clinical outcomes were underpowered due to relatively small numbers of trials.

Observational studies were mixed regarding the associations between n-3 FA intake or biomarkers and risk of MACE (where each study used its own combination of specific CVD outcomes). The strength of associations between higher levels of n-3 FA and lower risk of CVD outcomes, when found, were often larger than those in RCTs. While all observational studies adjusted associations for potentially confounding variables, the specific variables included in models varied greatly across observational studies. Furthermore, all observational studies compared higher intake levels of n-3 FA with lowest intake level, which included people who may have other nutrition deficiencies that may affect chronic disease risks but often cannot be "controlled for" in the analyses (resulting in residual, uncontrolled confounding).

Table A. Main findings of high, moderate, or low strength of evidence of significant effects or associations between omega- 3 fatty acids and outcomes
There is high strength of evidence for the following effects or associations of higher n-3 FA intake or biomarker levels and lower cardiovascular disease (CVD) risks or events:

- Marine oil* supplementation (or increased intake) and an increase in HDL-c
o RCTs (of mostly supplements)
o Summary net change in HDL-c: $0.9 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI} 0.2,1.6)$
- Marine oil* supplementation (or increased intake) and a decrease in Tg
o RCTs (of mostly supplements)
o Summary net change in Tg: $-24 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{Cl}-31,-18)$
- Marine oil* supplementation (or increased intake) and a decrease in total cholesterol to HDL-c ratio
o RCTs (of mostly supplements)
o Summary net change in Total:HDL-c ratio: -0.17 ( $95 \% \mathrm{Cl}-0.26,-0.09$ )
There is high strength of evidence for the following effects or associations of higher n-3 FA intake or biomarker levels and higher CVD risk:
- Marine oil* supplementation (or increased intake) and an increase in LDL-c
o RCTs (of mostly supplements)
o Summary net change in LDL-C: $2.0 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI} 0.4,3.6$ )
There is low strength of evidence for the following effects or associations of higher n-3 FA intake and lower CVD risks or events:
- Marine oil* higher dietary intake and a lower risk of ischemic stroke
o Observational studies (of total dietary intake), significant by metaregression: 0.51 ( $95 \% \mathrm{CI} 0.29$, 0.89) per g/d
*Statements about "marine oil" are based on all evidence of analyses of EPA+DHA+DPA, EPA+DHA, EPA, DHA, and DPA as supplements (e.g., fish oil) or as components of dietary intake (e.g., from fatty fish).

Abbreviations: CHD = coronary heart disease (also known as coronary artery disease), CHF = congestive heart failure, $\mathrm{CI}=$ confidence interval, CVD = cardiovascular disease, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HDL-c = high density lipoprotein cholesterol, HR = hazard ratio, LDL-c = low density lipoprotein cholesterol, n-3 FA = omega-3 fatty acids, RCT = randomized controlled trial, Tg = triglycerides.

## Table B. Main findings of high, moderate, or low strength of evidence of no significant effects or associations between omega-3 fatty acids and outcomes

There is high strength of evidence of no effect or association of n-3 FA intake or biomarker level and the following outcomes:

- Marine oil* supplementation (or increased dietary intake) and risk of major adverse cardiovascular event (MACE)
o RCTs (of mostly supplements); observational studies (of total dietary intake) also found no significant associations
o Summary effect size (RCTs): 0.96 ( $95 \% \mathrm{CI} 0.91,1.02$ )
- Marine oil* supplementation (or increased dietary intake) and all-cause death
o RCTs (of mostly supplements) supported by observational studies (of total dietary intake)
o Summary effect size (RCTs): 0.97 ( $95 \% \mathrm{Cl} 0.92,1.03$ )
o Observational studies (of total dietary intake): 0.62 ( $95 \% \mathrm{Cl} 0.31,1.25$ ) per g/d
- Marine oil* supplementation (or increased dietary intake) and sudden cardiac death (SCD)
o RCTs (of mostly supplements) supported by an observational study (of total dietary intake)
o Summary effect size (RCTs): 1.04 ( $95 \% \mathrm{Cl} 0.92$, 1.17)
- Marine oil* supplementation (or increased dietary intake) and coronary revascularization
o RCTs (of mostly supplements) supported by an observational study (of total dietary intake)
- Marine oil* supplementation (or increased dietary intake) and systolic or diastolic blood pressure
o RCTs (of mostly supplements)
o Summary net change in systolic blood pressure: $0.1 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.2,0.4)$
o Summary net change in diastolic blood pressure: $-0.2 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.4,0.5)$
There is moderate strength of evidence of no effect or association of n-3 FA intake or biomarker level and the following outcomes:
- Marine oil* supplementation (or increased dietary intake) and atrial fibrillation
o RCTs (of mostly supplements); observational studies of intake were inconsistent
- Purified DHA supplementation and systolic or diastolic blood pressure
o RCTs (of supplements only)
- Purified DHA supplementation and LDL-c
o RCTs (of supplements only)
- ALA supplementation (or increased dietary intake) and systolic or diastolic blood pressure
o RCTs (of mostly supplements)
- ALA supplementation (or increased dietary intake) intake and LDL-c, HDL-c, and Tg
o RCTs (of mostly supplements)

Table B. Main findings of high, moderate, or low strength of evidence of no significant effects or associations between omega-3 fatty acids and outcomes (continued)
There is low strength of evidence of no effect or association of n-3 FA intake or biomarker level and the following outcomes:

- Total n-3 FA higher dietary intake and stroke death
o Observational studies (of total dietary intake and biomarkers)
- Total n-3 FA higher dietary intake and myocardial infarction
o Observational studies (of total dietary intake)
- Marine oil* supplementation (or increased dietary intake) and cadiovascular disease (CVD) death
o Summary effect size (RCTs): 0.92 ( $95 \% \mathrm{Cl} 0.82,1.02)^{\dagger}$
o Observational studies (of total dietary intake): 0.88 ( $95 \% \mathrm{Cl} 0.82,0.95$ ) per g/d
- Marine oil* supplementation (or increased dietary intake) and coronary heart disease (CHD) death
o RCTs (of mostly supplements) imprecise
o Observational studies (of total dietary intake): 1.09 ( $95 \% \mathrm{Cl} 0.76,1.57$ ) per g/d
- Marine oil* higher dietary intake and coronary heart disease (CHD)
o Observational studies (of total dietary intake), supported by a single study of n-3 FA biomarkers
o Observational studies (of total dietary intake): 0.94 ( $95 \% \mathrm{Cl} 0.81,1.10$ ) per g/d
- Marine oil* supplementation (or increased dietary intake) and myocardial infarction
o Summary effect size (RCTs): 0.88 ( $95 \% \mathrm{Cl} 0.77,1.02)^{\dagger}$
- Marine oil* supplementation and angina pectoris
o RCTs (of supplements) with heterogeneous outcomes (definitions of angina pectoris)
- Marine oil* supplementation (or increased dietary intake) and congestive heart failure (CHF)
o RCTs (of mostly supplements) imprecise and could not be meta-analyzed, all nonsignificant
o Observational studies (of total dietary intake) significant by metaregression: 0.76 ( $95 \% \mathrm{Cl} 0.58$, $1.00)$ per g/d ( $\mathrm{P}<0.05$ )
- Marine oil* supplementation (or increased dietary intake) and total stroke (fatal and nonfatal ischemic and hemorrhagic stroke)
o Summary effect size (RCTs): 0.97 ( $95 \% \mathrm{Cl} 0.83,1.13$ )
o Observational studies (of total dietary intake): 0.68 ( $95 \% \mathrm{Cl} 0.53,0.87$ ) per g/d
- Marine oil* higher dietary intake and hemorrhagic stroke
o Observational studies (of total dietary intake): 0.61 ( $95 \% \mathrm{Cl} 0.34,1.11$ ) per g/d
- EPA higher dietary intake and CHD
o Observational studies (of total dietary intake)
- EPA higher biomarker levels and atrial fibrillation
o Observational studies (of biomarkers)
- DHA higher dietary intake and CHD
o Observational studies (of total dietary intake and biomarkers)
- DPA higher biomarker levels and atrial fibrillation
o Observational studies (of biomarkers)
- ALA higher dietary intake and CHD death and, separately, total CHD
o Observational studies (of total dietary intake); CHD death finding supported by one RCT (of supplementation) and one observational study of biomarkers
o Observational studies (of total dietary intake): CHD death 0.94 ( $95 \% \mathrm{Cl} 0.85,1.03$ ) per g/d
o Observational studies (of total dietary intake): CHD 0.97 ( $95 \% \mathrm{Cl} 0.92,1.03$ ) per g/d
- ALA higher dietary intake and atrial fibrillation
o Observational studies (of total dietary intake and biomarkers)
- ALA supplementation (or increased dietary intake) and CHF
o Observational studies (of total dietary intake and biomarkers), supported by one RCT (of supplementation)
* Statements about "marine oil" are based on all evidence of analyses of EPA+DHA+DPA, EPA+DHA, EPA, DHA, and DPA as supplements (e.g., fish oil) or as components of dietary intake (e.g., from fatty fish).
$\dagger$ There is low confidence that this summary estimate would remain suggestive of no effect with the addition of future trial data (and greater statistical power).

Abbreviations: ALA = alphalinolenic acid, CHD = coronary heart disease, CHF = congestive heart failure, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HDL-c = high density lipoprotein cholesterol, LDL-C = low density lipoprotein cholesterol, MACE = major adverse cardiovascular event (including cardiac and stroke events and death; variously defined by studies), n-3 FA = omega-3 fatty acids, RCT = randomized controlled trial, $\mathrm{SCD}=$ sudden cardiac death, $\mathrm{Tg}=$ triglycerides.

The overall findings for the effects of marine oil supplements on intermediate CVD outcomes remain largely unchanged since the original report. In this update, there were no significant effects found in 22 RCTs that compared marine oils ( $0.3-6 \mathrm{~g} / \mathrm{d}$ ) on systolic or diastolic BP compared with placebo. Thirty-nine RCTs evaluated LDL-c and HDL-c. Metaanalyses of the effect of marine oils on HDL-c and LDL-c found small, but statistically significant amounts (summary net change HDL-c $=0.9 \mathrm{mg} / \mathrm{dL}$ [95\% CI 0.2 to 1.7]; LDL-c $=2.0$ $\mathrm{mg} / \mathrm{dL}$ [95\% CI 0.4 to 3.6]). The clinical significance of these small increases in both HDL-c and LDL-c on CVD outcomes, particularly in combination, is unclear. For both lipid outcomes, no differences in effect across studies were found by marine oil dose, followup duration or population. The strongest effect of marine oils $(0.3-6 \mathrm{~g} / \mathrm{d})$ was found among the 41 RCTs of Tg. Meta-analysis found a summary net change of $-24 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-31$ to -18$)$, with no significant difference in effect based on population or followup time across studies. However, across trials, the effect was dose-dependent and also dependent on the studies' mean baseline Tg values. By metaregression, each increase of EPA+DHA dose by $1 \mathrm{~g} / \mathrm{d}$ was also associated with a greater net change Tg of $-5.9 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-9.9$ to -2.0$)$ and each increase in mean baseline Tg level by $1 \mathrm{mg} / \mathrm{dL}$ was associated with a greater net change Tg of $-0.15 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.22$ to -0.08 ). However, the few trials that directly compared marine oil doses did not consistently find consistently find a dose effect; although, marine oil doses $\geq 3 \mathrm{~g} / \mathrm{d}$ all resulted in larger reductions in Tg compared to lower doses, in contrast to doses $<3 \mathrm{~g} / \mathrm{d}$ which had smaller reductions in Tg compared to even lower doses. There were no observational studies evaluating these intermediate CVD outcomes.

In the original report, there was only one RCT of ALA (linseed oil) versus control oil (sunflower seed oil), conducted in the 1960s, that evaluated clinical event outcomes. In this update we identified only one additional RCT of ALA (plant source not reported) versus placebo (oleic acid) in participants with a history of MI that reported clinical outcomes. Given the sparseness of trials of the effect on clinical CVD outcomes of higher ALA intake and the differences between the two trials, no conclusion can be drawn regarding effect of ALA on CVD outcomes. For intermediate outcomes, five ALA RCTs (with doses ranging from 1.4 to $5.9 \mathrm{~g} / \mathrm{d}$ ) evaluated BP outcomes, and four of the five RCTs also evaluated LDL-c, HDL-c, Tg, or Total:HDL-c ratio (2 trials) outcomes. All found no significant differences in these outcomes between ALA and placebo. Thirteen observational studies evaluated ALA intake. The large majority of analyses found no significant associations; only two studies found any significant associations between higher ALA intake and clinical outcomes (reduced all-cause death, SCD, and CHD death risks).

The potential intake threshold-effects of n-3 FA on CVD events could not be determined from the RCTs because there were limited number of RCTs for many outcomes and most RCTs did not find significant effects. Using data from observational studies, the linear dose-response and potential threshold effects of n-3 FA on several CVD events were tested by meta-analytical techniques. There was a significant association between higher EPA and DHA intake and lower risk of ischemic stroke across a median dosage range of 0.025 to $0.6 \mathrm{~g} / \mathrm{d}$ (effect size per g/d = 0.51 ; $95 \%$ CI 0.29 to 0.89 ), but no dose-response relationships found between EPA and DHA intake and both CHD and hemorrhagic stroke. The interpretations of the threshold-effects (in observational studies) were limited because differences in associations at lower doses (statistically significant associations between higher intake and lower risk) and associations at higher doses (no significant associations between intake and outcome) were generally similar regardless of the cut point chosen between lower and higher dose analyses.

No differences in effects or associations were found between different populations (healthy or general population, at increased risk for CVD—largely due to dyslipidemia, or with CVD). However, this conclusion is weak given that few studies compared populations, few RCTs were conducted in healthy populations and few observational studies were conducted in at risk or CVD populations.

## Limitations

Overall, both RCTs and observational studies (i.e., longitudinal observational and nested case-control studies) included in this systematic review generally had few risk of bias concerns. For clinical CVD outcomes, all but one of the RCTs was conducted in either high risk individuals or people with existing CVD. In contrast, most observational studies examining the associations between dietary n-3 FA intake or biomarkers of n-3 FA intake and clinical outcomes were conducted in generally healthy populations. Few trials compared n-3 FA dose, formulation, or source. No trial compared different n-3 to n-6 FA ratios of supplements or intake. None of the observational studies attempted to determine a threshold effect of any associations between n-3 FA and the outcome of interest.

There are numerous differences between RCTs and observational studies, making the comparisons across the two study designs difficult to make. Of note, the doses of marine oil supplements (EPA+DHA) in RCTs were often much higher than the highest intake reported for observational studies. Furthermore, not all observational studies explicitly included n-3 FA supplements in their assessment of intake and very few of the RCTs attempted to account for background fish or n-3 FA intake as an effect modifier.

While this report represents a complete systematic review, it does not encompass all trials or longitudinal observational studies that report on CVD and intermediate outcomes. Particularly, if one includes small studies (trials with <30 participants per study group or observational studies with <100 participants, several hundred more studies could potentially have met eligibility criteria. Due to time and resource limitations, we restricted the review to the approximately 100 studies that are most likely to have adequately addressed the primary research questions of interest.

## Future Research Recommendations

Future RCTs should fully characterize both the preparations of n-3 FA interventions and placebos used for the intervention in terms of the FA composition and molecular form of the FA (e.g., ethyl esters, Tg), as well as indicating their sources. The placebo foods and oils should have the same caloric density and to the extent possible similar food or oil types as the source of n-3 FA. The composition of the background diet should also be reported, as should FA composition, macronutrient content and whether the participants were weight-stable. Researchers are encouraged to use standard, common CVD outcomes to allow comparison across studies. Assessment of n-3 FA status and intake should be evaluated at study entry and post-intervention in all study participants using to better understand potential changes in n-3 FA intake in populations with different background diets (e.g., whether the effect of supplementation differs in people with high- or low-fish diets). If trials include participants with a broad range of n-3 FA status or intake (e.g., with both high- and low-fish diets), subgroup analyses should be conducted to evaluate possible differential effects based on $\mathrm{n}-3$ these variables. The effects (or lack thereof) of marine oils (EPA+DHA) on BP, LDL-c, HDL-c, and Tg are well established so additional

RCTs on these intermediate outcomes alone are unlikely to add any new knowledge, and therefore are not recommended.

There is an ongoing need to improve self-reported dietary assessment methods and food databases for all nutrients including n-3 FA. As national dietary patterns shift and new processed foods are introduced into the marketplace, food composition tables used to analyze food frequency questionnaire data need to be updated to ensure accurate estimation of n-3 FA (and other nutrient) intake. Similar to trial registries, a data repository for raw observational study data would greatly improve the transparency of data analyses (potentially reduce both reporting and publication biases) and the appropriateness and methodology of meta-analytical techniques for pooling observational studies. An individual participant-level meta-analysis of observational studies of marine oils could address limitations of the study-level meta-analyses that are currently feasible.

## Conclusions

Results from the RCTs of clinical event outcomes are applicable only to at-risk-of-CVD and CVD populations because there is insufficient trial evidence of the effect of n-3 FA on clinical CVD outcomes in healthy populations. Results from the RCTs of intermediate outcomes; however, are applicable to all populations (healthy, at risk, and with CVD) since the trials included a range of people from the different populations. In contrast, results from observational studies (which did not evaluate intermediate outcomes) are applicable only to generally healthy populations. We graded the strength of the body of evidence for each intervention/exposure and comparison of intervention, and for each outcome by assessing the number of studies, their study designs, the study limitations (i.e., risk of bias and overall methodological quality), the directness of the evidence to the Key Questions, the consistency of study results, the precision of any estimates of effect, the likelihood of reporting bias, and the overall findings across studies. We concluded that there is insufficient evidence regarding the effect of or association between total n-3 FA (ALA + marine oils [EPA+DHA $\pm$ DPA]) and clinical or intermediate outcomes. There is low strength of evidence of no association between total n-3 FA intake and stroke death, and total MI (each association based on longitudinal observational studies). For marine oil (EPA $+\mathrm{DHA} \pm \mathrm{DPA}$ ), there is insufficient evidence for most outcomes of interest but there is low to high strength of evidence of a beneficial effect of higher marine oil intake for selected CVD and intermediate outcomes. Specifically, there is high strength of evidence that marine oils clinically and statistically significantly lower Tg-possibly with greater effects with higher doses and in people with higher baseline Tg . There is also high strength of evidence that marine oils statistically, but arguably not clinically, significantly raise both HDL-c and LDL-c. There is also high strength of evidence that marine oil significantly lowers Total:HDL-c ratio. There is low strength of evidence that marine oil supplementation lowers risk of ischemic stroke. There is a high strength of evidence of no effect of marine oil on risk of MACE, all-cause death, sudden cardiac death, coronary revascularization, and blood pressure; moderate strength of evidence of no effect of marine oil on risk of atrial fibrillation; and low strength of evidence of no associations of marine oil intake and cardiovascular death, CHD death, CHD, myocardial infarction, angina pectoris, CHF, total stroke, or hemorrhagic stroke.

For individual n-3 FA, there is insufficient evidence regarding the effect of or association with EPA, DHA, DPA, SDA, or ALA (specifically) and most CVD clinical outcomes. For EPA,
there is low strength of evidence of no association between EPA intake and CHD and between EPA biomarkers and AFib. For DHA, there is moderate strength of evidence of no effect of purified DHA supplementation on BP or LDL-c and low strength of evidence of no association between DHA intake and incident CHD (from observational studies). For DPA, there is low strength of evidence of an association between higher DPA biomarker levels and lower risk of AFib. For ALA, there is moderate strength of evidence of no significant effect of ALA intake on BP, LDL-c, HDL-c, or Tg. There is low strength of evidence of no association between ALA intake or biomarker level and CHD or CHD death, AFib, or CHF, based on observational studies.

There is insufficient evidence of direct comparisons between marine oil and ALA intake on CVD outcomes. Across studies, the indirect comparison between marine oil and ALA is unclear, largely because there is insufficient evidence regarding the effect or association of ALA with clinical CVD outcomes. However, where there is high strength of evidence of significant effects of marine oil on improving Tg and HDL-c, there is moderate strength of evidence of no effect of ALA intake on these intermediate outcomes. No RCTs examined the additive effects of $\mathrm{n}-3$ FA versus the effects of individual n-3 FA.

## Introduction

## Background

Since the first ecological study published in the late 1970s noted a relatively low cardiovascular (CV) mortality in a Greenland Eskimo population with high fish consumption, ${ }^{1}$ there have been hundreds of observational studies and clinical trials conducted to evaluate the effect of omega -3 fatty acids ( $\mathrm{n}-3 \mathrm{FA}$ ) on CV disease (CVD) and its risk factors and intermediate markers. The n-3 FA (including alphalinolenic acid [ALA], stearidonic acid [SDA], eicosapentaenoic acid [EPA], docosapentaenoic acid [DPA], and docosahexaenoic acid [DHA]) are a group of long-chain and very-long-chain polyunsaturated fatty acids (PUFA) that are substrates for the synthesis of eicosanoids and are important components of cell membranes that impact fluidity. Eicosanoids (including prostaglandins, thromboxanes, and leukotrienes) have wide ranges of physiologic effects and play a key role in inflammation regulation. The metabolic pathway of n-3 FA is shown in Figure 1. ALA is the shortest n-3 FA from which all other n-3 FA, if not ingested preformed, are metabolically derived. ALA is an essential nutrient; it cannot be made by the human body and must come from the diet. SDA can be formed from ALA via $\Delta 6$ desaturase, the rate-limiting enzyme in the pathway. If SDA enters the metabolic pathway preformed , between 15 and 30 percent can be elongated and saturated to EPA. EPA can be converted to DPA and vice versa. However, the elongation and desaturation of ALA to EPA and DHA is inefficient. Based on stable-isotope tracer studies the estimated conversion rates are broad, ranging from 0.2 to 5 percent. ${ }^{2}$ Major dietary sources of ALA include soybean and canola oils, some nuts, and flaxseed. The major dietary sources of EPA and DHA are fish, other marine life, and marinederived supplements. There is no naturally occurring source of SDA that, per serving, provides amounts of n-3 FA approaching levels (of EPA and DHA) present in oily fish. Naturally occurring sources of SDA-hemp and echium seed oils-are not consumed by the general population. In the future, though, SDA may be present in genetically modified
soybeans.
Since the publication of the original Agency for Healthcare and Research Quality (AHRQ) n-3 FA systematic reviews in 2004, ${ }^{3,4}$ the topic of n-3 FA and CVD has remained controversial and dynamic. This topic has been evaluated by several expert panels that were

Figure 1. Metabolic pathway of omega-3 fatty acids

Abbreviations: ALA = alphalinolenic acid, SDA = stearidonic acid, EPA = eicosapentaenoic acid, DPA = docosapentaenoic acid, DHA = docosahexaenoic acid, n-3 = omega-3 fatty acids
considering whether recommendations or reference values for intakes of EPA and DHA were warranted, either through naturally occurring sources of n-3 FA (e.g., fish consumption) and/or through the use of dietary supplements and fortified foods. ${ }^{5-8}$

In 2002, the Institute of Medicine (IOM) considered the evidence inadequate to establish an estimated average requirement for $\mathrm{n}-3 \mathrm{FA} .{ }^{6}$ Thus the IOM established only adequate intake values for ALA, based on current population ALA intake and an apparent absence of deficiency symptoms. For healthy adults, the adequate intake values for ALA are $1.1 \mathrm{~g} / \mathrm{d}$ for females and $1.6 \mathrm{~g} / \mathrm{d}$ for males. ${ }^{6}$ After evaluating evidence linking the very-long-chain n-3 FA-EPA and DHA - to coronary heart disease (CHD, also known as coronary artery disease) and stroke, the IOM panel suggested that n-3 FA may provide beneficial health effects with respect to CHD and stroke ; the acceptable macronutrient distribution range (a range of intakes that is associated with reduced risk of chronic diseases while providing adequate intakes of essential nutrients) for ALA was set at 0.6 to 1.2 percent of energy (roughly equivalent to 1 to $3 \mathrm{~g} / \mathrm{d}$ ), where 10 percent of this range can be consumed as EPA and/or DHA. ${ }^{6}$ For comparison, the mean intake of ALA in the United States has been estimated at 0.6 percent of energy intake (standard deviation $1.0 \%$ ), ${ }^{9}$ equivalent to approximately $1.4 \mathrm{~g} / \mathrm{d}$. This intake level, is fairly consistent across developed countries ( $0.3-1.0 \%$ of energy). However, estimated EPA and DHA intake in the United States are only $0.05 \mathrm{~g} / \mathrm{d}$ and $0.08 \mathrm{~g} / \mathrm{d}$, respectively. In contrast, mean intake in South Korea is $0.4 \mathrm{~g} / \mathrm{d}$ of EPA and DHA, combined. ${ }^{9}$

SDA and DPA have only infrequently been analyzed in regards to their association with CVD. Three other expert reports evaluated the potential health benefits of fish/seafood consumption. ${ }^{5,7,8}$ Based primarily on the availability of observational study data, these panels consistently suggested that regular consumption of fish and seafood is associated with lower risk of CHD and cardiac death. These recommendations were based primarily on assumptions of benefits from EPA and DHA and their content in fish and seafood.

However, determination of n-3 FA intake is problematic, both for population recommendations and in regards to research. In practice, all nutrients are quantified using a nutrient database, e.g., the U.S. Department of Agriculture National Nutrient Database for Standard Reference (http://ndb.nal.usda.gov/). The quantity of a nutrient is then estimated by the standard amount of nutrients in foods that are indexed in the nutrient database multiplied by the amount and frequency of the food consumption. However, n-3 FA in foods are not well estimated in the nutrient database and questionnaires commonly do not ask about cooking oils or dressings and may not ask about supplements (so that n-3 FA intake is estimated only from fish consumption); therefore quantification of n-3 FA intake from food frequency questionnaires is poor. Furthermore, some questionnaire do not include portion size, so further estimation or extrapolation of intake is required.

There have been secular trends in the prevention and treatment of CVD over the past several decades, particularly since the 2004 AHRQ reports on n-3 FA and CVD. These trends may have had an important impact on the potential effect or association between n-3 FA intake and CVD outcomes. Important among these trends are the lower rates of cardiac and cerebrovascular disease, concomitant with higher rates of treatment and control of dyslipidemia and hypertension. For at least the past 20 years American adults are increasingly likely to be treated with statins, antihypertensives, and low-dose aspirin. All of these pharmacologic interventions act on metabolic and biochemical pathways that n-3 FA also impact and this confounding may impact the purported CV benefits of n-3 FA, including lipid metabolism, blood pressure (BP) and vascular homeostasis, and inflammatory and coagulation pathways. These
treatment trends may have contributed to the lower population-level CV benefit of higher n-3 FA intake because the underlying risk of CVD is now lower, hence, diminishing the potential impact of n-3 FA intake. Furthermore, diagnostic criteria for CVD events (e.g., myocardial infarction) and CV risk factors (e.g., metabolic syndrome) have been refined over time which may make older studies less applicable in terms of their outcomes and populations.

## Scope and Key Questions

## Scope of the Review

The National Institutes of Health’s Office of Dietary Supplements (ODS) has a long history of commissioning AHRQ-based systematic reviews and research methodology reports for nutrition-related topics (http://ods.od.nih.gov/Research/Evidence-Based_Review_Program.aspx). n-3 FA and their potential relationship to a broad range of health outcomes formed the basis for nine of these systematic reviews published between 2004 and 2006 and also served as examples for several methodological reports. ${ }^{10-23}$

There are ongoing concerns in the scientific community regarding systematic biases and random errors in the determination of intakes of n-3 FA from dietary and supplement sources using currently available assessment tools. The limitations of the current methods have been discussed elsewhere. ${ }^{24-26}$ To date, no alternate methods are available. Until "error-free" or "biasfree" methodologies are developed, it is crucial to evaluate the available data with these methodological quality and limitations in mind. Nutrient biomarkers can provide an objective measure of dietary status. ${ }^{27}$ However, the correspondence between intake and biomarker concentration not only reflects recent intake but subsequent metabolism (e.g., elongation, desaturation, metabolism to bioactive compounds). Current biomarkers used to estimate n-3 FA intake include ALA, EPA, DHA, and, less frequently, SDA and DPA, measured in adipose tissue, erythrocytes, plasma, or plasma phospholipids. ${ }^{27-29}$ Adipose tissue FA are thought to reflect long-term intake, erythrocyte FA are thought to reflect the previous 120 day intake, and plasma FA are thought to reflect more immediate intake. ${ }^{28}$

Several recent systematic reviews of randomized controlled trials (RCTs) in individuals with diagnosed CVD or at high risk of CVD have suggested mixed results as to whether there are benefits of very-long-chain PUFA (EPA and DHA) for reducing the risk of adverse CV outcomes. ${ }^{21,30-36}$ Reasons for the apparent inconsistent scientific conclusions among several of the expert panels and the more recent systematic reviews are varied but may relate, in part, to whether the n-3 FA exposures were from fish (or other marine) or plant sources, or from dietary supplements. The expert reviews also vary as to whether they relied primarily on observational studies or RCTs. ${ }^{21,}{ }^{30-36}$ Studies of different designs each have their own strengths and weakness that may result in differences in conclusions. For example, observational studies based on selfreported dietary assessments (e.g., food frequency questionnaires) may inaccurately estimate n-3 FA intake; RCTs of specific fish or other n-3 FA-rich food may impose an artificial dietary pattern that might not be applicable to the general population; RCTs of supplements might not fully account for differences in background n-3 FA intake; studies using either study design may have subtle differences in eligibility criteria, e.g., length of followup duration, or inclusion of ALA, EPA and DHA or only EPA and DHA, that significantly impacted the final conclusions. Since there are limitations to different study designs and ways of assessing associations, it is of interest to systematically compare results across different study types (e.g., interventional vs. prospective cohort studies) and different ways of evaluating exposures, and to account for
differences in background n-3 FA intake. Also of interest is a systematic evaluation of possible reasons for inconsistencies between observational and RCT findings, ${ }^{37}$ in particular a tabulation of causality-related study features.

The purpose of the current systematic review is twofold: 1) to update earlier reviews of the state-of-the science on the topic of the effects of n-3 FA on CVD, ${ }^{4}$ and selected CVD risk factors and intermediate markers of CVD, ${ }^{3}$ and 2 ) to use this new review to collect additional information that would enhance the usefulness of this report for policy and clinical applications. The primary target audience for this report is clinical and nutrition researchers and policymakers, including ODS and panels revising dietary intake recommendations. The 2004 reviews screened about 7,500 abstracts and retrieved and screened 768 full text articles for potentially relevant human data. For CVD outcomes, 11 RCTs and one prospective cohort study reported outcomes in individuals with diagnosed CVD, and 22 prospective cohort studies and one RCT reported data on the general population. The report on intermediate CVD outcomes included the 25 largest RCTs with lipid outcomes, an existing systematic review of BP, ${ }^{38}$ and six RCTs of BP in people with diabetes (who had been excluded from the existing systematic review). This review updates the previous review for the outcomes included and also expands the scope to include additional CVD outcomes (peripheral vascular disease, congestive heart failure (CHF), and arrhythmias); it updates BP and plasma lipid outcomes from, and adds incident hypertension to, the 2004 review of CVD risk factors and intermediate markers of $\mathrm{CVD}^{3}$; it adds associations between biomarkers of n-3 FA intake and outcomes.

## Key Questions

The Key Questions address both issues of efficacy (i.e., causal relationships from trials) as well as associations (i.e., prospective observational cohort study associations of n-3 FA intake and/or biomarkers with long-term outcomes; biomarker associations reported in RCTs). Compared with the Key Questions from the 2004 reports, the current Key Questions expand the scope of the review to include additional CV outcomes (BP, CHF, and arrhythmias), focus on the intermediate outcomes plasma lipids and BP, adds the intermediate outcome hypertension, and include associations between biomarkers of intake and outcomes.

1. What is the efficacy or association of n-3 FA (EPA, DHA, EPA+DHA, DPA, SDA, ALA, or total n-3 FA) exposures in reducing CVD outcomes (incident CVD events including all-cause death, CVD death, nonfatal CVD events, new diagnosis of CVD, peripheral vascular disease, CHF, major arrhythmias, and hypertension diagnosis) and specific CVD risk factors (BP, key plasma lipids)?

- What is the efficacy or association of n-3 FA in preventing CVD outcomes in people
o Without known CVD (primary prevention)
o At high risk for CVD (primary prevention), and
o With known CVD (secondary prevention)?
- What is the relative efficacy of different n-3 FA on CVD outcomes and risk factors?
- Can the CVD outcomes be ordered by strength of intervention effect of $n-3$ FA?

2. n-3 FA variables and modifiers:

- How does the efficacy or association of n-3 FA in preventing CVD outcomes and with CVD risk factors differ in subpopulations, including men, premenopausal women, postmenopausal women, and different age or race/ethnicity groups?
- What are the effects of potential confounders or interacting factors-such as plasma lipids, body mass index, BP, diabetes, kidney disease, other nutrients or supplements, and drugs (e.g., statins, aspirin, diabetes drugs, hormone replacement therapy)?
- What is the efficacy or association of different ratios of n-3 FA components in dietary supplements or biomarkers, on CVD outcomes and risk factors?
- How does the efficacy or association of n-3 FA on CVD outcomes and risk factors differ by ratios of different n-3 FA-DHA, EPA, and ALA, or other n-3 FA?
- How does the efficacy or association of n-3 FA on CVD outcomes and risk factors differ by source (e.g., fish and seafood, common plant oils (e.g., soybean, canola), fish oil supplements, fungal-algal supplements, flaxseed oil supplements)?
- How does the ratio of n-6 FA to n-3 FA intakes or biomarker concentrations affect the efficacy or association of n-3 FA on CVD outcomes and risk factors?
- Is there a threshold or dose-response relationship between n-3 FA exposures and CVD outcomes and risk factors? Does the study type affect these relationships?
- How does the duration of intervention or exposure influence the effect of $n-3$ FA on CVD outcomes and risk factors?
- What is the effect of baseline n-3 FA status (intake or biomarkers) on the efficacy of $n$ - 3 FA intake or supplementation on CVD outcomes and risk factors?

3. Adverse events:

- What adverse effects are related to n-3 FA intake or biomarker concentrations (in studies of CVD outcomes and risk factors)?
- What adverse events are reported specifically among people with CVD or diabetes (in studies of CVD outcomes and risk factors)?

## Analytic Framework

To guide the assessment of studies that examine the association between n-3 FA intake and CV outcomes, the analytic framework maps the specific linkages associating the populations of interest, the exposures, modifying factors, and outcomes of interest (Figure 2). The framework graphically presents the key components of well-formulated study questions:

1. Who are the participants (i.e., what is the population and setting of interest, including the diseases or conditions of interest)?
2. What are the interventions?
3. What are the outcomes of interest (intermediate and health outcomes)?
4. What study designs are of value?

Specifically, this analytic framework depicts the chain of logic that evidence must support to link the intervention (exposure to n-3 FA) to improved health outcomes.

Figure 2. Analytic framework for omega-3 fatty acid exposure and cardiovascular disease

This framework concerns the effect of n-3 FA exposure (as a supplement or from food sources) on CVD and CVD risk factors. Populations of interest are noted in the top rectangle, exposure in the oval, outcomes in the rounded rectangles, and effect modifiers in the hexagon.

* Specifically, cardiovascular medications, statins, antihypertensives, diabetes medications, hormone replacement regimens.
$\dagger$ Systolic blood pressure, diastolic blood pressure, mean arterial pressure, high density lipoprotein cholesterol (HDLc), Iow density lipoprotein cholesterol (LDL-c), total/HDL-c ratio, LDL-c/HDL-c ratio, triglycerides. $\ddagger$ Many other intermediate outcomes are likely in the causal pathway between n-3 FA intake and cardiovascular outcome, but only blood pressure and plasma lipids were included in the review.

Abbreviations: ALA = alphalinolenic acid, CHD = coronary heart disease, CHF = congestive heart failure, CKD = nondialysis-dependent chronic kidney disease, CMS = cardiometabolic syndrome, CVA = cerebrovascular accident (stroke), CVD = cardiovascular disease, $\mathrm{DHA}=$ docosahexaenoic acid, $\mathrm{DM}=$ diabetes mellitus, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, FA = fatty acid, HDL-c = high density lipoprotein cholesterol, HTN = hypertension, LDL-c = low density lipoprotein cholesterol, MI = myocardial infarction, n-3 = omega-3, n-6 = omega-6, $\mathrm{PCI}=$ percutaneous coronary intervention, SDA $=$ stearidonic acid.

## Methods

The present review evaluates the effects of, and the associations between, omega-3 fatty acids (n-3 FA)—including alphalinolenic acid (ALA), stearidonic acid (SDA), eicosapentaenoic acid (EPA), docosapentaenoic acid (DPA), and docosahexaenoic acid (DHA) and n-3 FA biomarkers- and cardiovascular disease (CVD) outcomes. The Brown Evidence-based Practice Center (EPC) conducted the review based on a systematic review of the published scientific literature using established methodologies as outlined in the Agency for Healthcare Research and Quality (AHRQ) Methods Guide for Effectiveness and Comparative Effectiveness Reviews. ${ }^{39}$

The review was conducted in parallel with a systematic review of n-3 FA and child and maternal health, conducted by another Evidence-based Practice Center (EPC). Several aspects of the review were coordinated, including eligibility criteria and search strategies regarding interventions and exposures structure of the reviews, and assessments of the studies’ risk of bias, strength of the bodies of evidence, and extraction of study characteristics needed to assess causality.

## Topic Refinement and Review Protocol

We convened a Technical Expert Panel (TEP) to help refine the research questions and protocol. The TEP included five experts in nutrition, n-3 FA research specifically, CVD epidemiology, and cardiology. Also included in the discussions with the TEP were the Director of and a Senior Scientist at the Office of Dietary Supplements (ODS), and the AHRQ Task Order Officer. We discussed the Key Questions, analytic framework, study eligibility criteria, literature search, and analysis plans.

In regards to the populations of interest, we explicitly expanded the definition of the at risk for CVD population to include adults with cardiometabolic syndrome (and related conditions) and nondialysis dependent chronic kidney disease. Regarding the interventions of interest, we discussed the changes from the original AHRQ reports on n-3 FA, specifically that we included only studies that quantify n-3 FA content of the intervention, and that we added n-3 FA biomarkers as an exposure of interest. We also clarified that we excluded weight loss interventions that included n-3 FA as part of the intervention. Weight-loss studies, by definition need to create energy deficits; interventions generally aim to reduce total energy intake and/or increasing energy expenditure. Energy deficits trigger metabolic changes including altering lipid metabolism. Since CVD outcomes were the main outcome of interest, weight loss is a major confounder that may be in the causal pathway between exposures of interest (i.e., n-3 FA) and CVD outcomes. Regarding outcomes of interest, we refined the list of "major lipids" of interest to include only low density lipoprotein cholesterol (LDL-c), high density lipoprotein cholesterol (HDL-c), triglycerides (Tg), LDL-c to HDL-c ratio, and total cholesterol to HDL-c ratio. Compared to the original n-3 FA and CVD outcome report, we added peripheral vascular disease, arrhythmia events, congestive heart failure (CHF), and incident hypertension. We discussed a number of potential modifiers of interest to be searched for, including demographic features, weight, blood pressure (BP), source and type of n-3 FA, exposure duration, C reactive protein level, and specific co-interventions (i.e., statins, vitamin E).

It was agreed to maintain a minimum duration of followup of 1 month for intermediate outcomes (lipids and BP) and 1 year for all clinical outcomes. We agreed to include only randomized controlled trials (RCT) of specific comparisons of interventions and large, prospective, longitudinal observational studies of exposure (either baseline dietary intake or
biomarker level). We also agreed to include the RCTs that are largest or report subgroup or factorial analyses, and the largest observational studies to constrain the total number of included studies to approximately 75 to 100 . The search strategy was refined based on suggestions from the TEP. The TEP agreed that the primary literature search would be conducted for the period from 2002 to the present to capture studies published since the original EPC report, with older studies to come from existing systematic reviews including the original EPC report. For new topics (e.g., biomarkers, peripheral vascular disease), the TEP agreed that searches back to 2000 would be sufficient to capture relevant analyses.

In addition, in separate discussions with the Office of Dietary Supplements (ODS) representative and our Task Order Officer (TOO) we considered how and whether to assess the concept of causality, particularly for the observational studies. After discussion of the Bradford Hill criteria and related issues regarding causality, ${ }^{40}$ we agreed upon the creation of an appendix table (Appendix G) that provides the study-level data for items that may be pertinent for users of this report to assess causality.

Furthermore, we had joint discussions with the Southern California EPC-which conducted a parallel report of n-3 FA and maternal and child health-and our TOO and the ODS representative to coordinate our protocols and processes. The protocol was entered into the PROSPERO register (registry number CRD42014015602).

## Literature Search

We conducted literature searches of studies in MEDLINE®, both the Cochrane Central Trials Registry ${ }^{\circledR}$ and Cochrane Database of Systematic Reviews ${ }^{\circledR}$, Embase ${ }^{\circledR}$, and CAB Abstracts ${ }^{\circledR}$ from 2002 to 8 June 2015 (to overlap with the last search run for the 2004 reviews). We searched earlier publications back to 2000 for the newly added outcomes (peripheral vascular disease, CHF, arrhythmias, hypertension) and for biomarkers of n-3 FA intake. We also rescreened and included all studies from the original reviews that met current eligibility criteria. We revised the search strategy used in the original reviews to capture new terms for n-3 FA, biomarkers, and additional outcomes. In electronic searches, we combined terms for n-3 FA (and biomarkers), CVD and risk factors (BP, plasma lipids, hypertension), limited to humans, English language, and relevant research designs. Titles and abstracts were screened to identify articles relevant to each Key Questions. We also reviewed reference lists of related systematic reviews for other potentially eligible studies. We invited TEP members to provide additional citations. In addition, a call for potentially relevant articles was posted on the Federal Register (in lieu of Scientific Information Packets), but yielded no additional studies. Appendix A displays the current complete search strategy.

## Study Eligibility Criteria

The current eligibility criteria are mostly similar to the criteria used in the original 2004 review. The populations remain the same. The interventions and exposures have been expanded to include n-3 FA biomarkers. The list of CVD outcomes of interest has been expanded. Similar study designs were included.

For all Key Questions, the eligibility criteria are:
Populations

- Healthy adults ( $\geq 18$ years) without CVD or with low to intermediate risk for CVD
- Adults at high risk for CVD (e.g., with diabetes, cardiometabolic syndrome, hypertension, dyslipidemia, nondialysis dependent chronic kidney disease)
- Adults with clinical CVD (e.g., history of myocardial infarction [MI], angina, stroke, arrhythmia)
- Exclude populations chosen for having a non-CVD or nondiabetes-related disease (e.g., cancer, gastrointestinal disease, rheumatic disease, dialysis)

Interventions/Exposures

- n-3 FA supplements
- n-3 FA supplemented foods (e.g., eggs)
- n-3 FA content in diet
- Biomarkers of n-3 FA intake
- n-3 FA content of food or supplements must have been explicitly quantified (by any method). Therefore, studies such as those of fish diet where only servings per week were defined or Mediterranean diet studies without n-3 FA quantified were excluded. The n-3 FA quantification could be of total n-3 FA, of a specific n-3 FA (e.g., ALA) or of combined EPA+DHA ("marine oil").
- Exclude mixed interventions of n-3 FA and other dietary or supplement differences (e.g., n-3 FA and vitamin E versus placebo; n-3 FA as part of a low fat diet versus usual diet). However, factorial design (and other) studies that compared (for example) n-3 FA versus control, with or without another intervention (e.g., statins) were included.
- Exclude n-3 FA dose $\geq 6 \mathrm{~g} / \mathrm{d}$, per the original review's protocol based on the assessment that n-3 FA intake above this amount is impractical and has little relevance on health care recommendations.
- Exclude weight loss interventions

Comparators

- Placebo or no n-3 FA intervention
- Different n-3 FA source intervention
- Different n-3 FA concentration intervention
- Different n-3 FA dietary exposure (e.g., comparison of quantiles)
- Different n-3 FA biomarker levels (e.g., comparison of quantiles)

## Outcomes

- All-cause death
- Cardiovascular (CV), cerebrovascular, and peripheral vascular events:

0 Fatal vascular events (e.g., due to MI, stroke)
o Total incident vascular events (e.g., MI, stroke, transient ischemic attack, unstable angina, major adverse CV events [MACE]; total events include fatal and nonfatal events; total stroke includes ischemic and hemorrhagic stroke)
o Coronary heart disease (also known as coronary artery disease), new diagnosis
o CHF, new diagnosis
o Cerebrovascular disease, new diagnosis
o Peripheral vascular disease, new diagnosis
o Ventricular arrhythmia, new diagnosis, including sudden cardiac death
o Supraventricular arrhythmia (including atrial fibrillation), new diagnosis
o Major vascular interventions/procedures (e.g., revascularization, thrombolysis, lower extremity amputation, defibrillator placement)

- Major CVD risk factors (intermediate outcomes):
o BP (new-onset hypertension, systolic, diastolic, and mean arterial pressure)
o Key plasma lipids (i.e., HDL-c, LDL-c, total/HDL-c ratio, LDL-c/HDL-c ratio, Tg )
- Adverse events (e.g., bleeding, major gastrointestinal disturbance), only from intervention studies of supplements

## Timing

- Clinical outcomes, including new-onset hypertension (all study designs): $\geq 1$ year followup (and intervention duration, as applicable)
- Intermediate outcomes (BP and plasma lipids) (all study designs): $\geq 1$ month followup
- Adverse events (all study designs): no minimum followup

## Setting

- Community-dwelling (noninstitutionalized) individuals

Study Design

- RCTs (all outcomes)
- Randomized cross-over studies (BP and plasma lipids, adverse events), minimum washout period to be determined
- Prospective nonrandomized comparative studies (clinical outcomes, adverse events)
- Prospective cohort (single group) studies, where groups were compared based on n-3 FA intake or intake biomarker values (clinical outcomes). Observational studies must have reported multivariate analyses.
- Exclude: Retrospective or case control studies or cross-sectional studies (but include prospective nested case control studies). Studies must have had measures of intake prior to outcome.
- Minimum sample sizes

Due to the very large number of potentially eligible studies (more than 400), we applied arbitrary thresholds based on sample size, followup duration, and whether subgroup or interaction analyses were reported. These were designed to give preference to larger studies with longer followup duration or that reported interaction analyses of interest.
o RCTs

- We aimed for a minimum of about 25 RCTs for each of the BP and plasma lipid outcomes. We preferentially included RCTs that reported relevant subgroup, interaction, or factorial analyses.
- For RCTs with BP or lipid outcomes with subgroup, interaction, or factorial analyses, we included parallel design RCTs with a minimum of 30 participants per arm, factorial RCTs with a minimum of 30 participants per n-3 FA intervention, and crossover trials with a minimum of 20 participants.
- For RCTs with lipid outcomes without subgroup analyses, we included parallel design RCTs with a minimum of 200 participants per arm, factorial RCTs with a minimum of 200 participants per n-3 FA intervention, and crossover trials with a minimum of 100 participants.
- For RCTs with BP outcomes without subgroup analyses, if followup was $\geq 6$ months, we included all RCTs; if followup was $<6$ months ( $\geq 1$ month), we included parallel design RCTs with a minimum of 80 participants per arm, factorial RCTs with a minimum of 80 participants per n-3 FA intervention, and crossover trials with a minimum of 40 participants.
- For RCTs with CVD event outcomes, we included all RCTs with at least 10 participants per arm.
o Longitudinal observational studies
- We aimed for a minimum of about 10 observational studies for each broad clinical outcome (see bullets below) and also for dietary marine oils, dietary ALA, marine oil biomarkers, and ALA biomarkers.
- For cardiac event outcomes, we included observational studies with at least 10,000 participants.
- For death outcomes, we included observational studies with at least 10,000 participants.
- For stroke event outcomes, we included observational studies with at least 3000 participants.
- For arrhythmia event outcomes, we included observational studies with at least 2000 participants.
- For CHF event outcomes, we included observational studies with at least 700 participants.
- For peripheral vascular disease event, incident hypertension, MACE, and revascularization outcomes, we included observational studies with at least 500 participants.
- We screened smaller sample size observational studies (starting with the largest studies) to include additional studies of ALA biomarkers, regardless of the outcomes analyzed.
o In all instances, if a study met eligibility criteria for any outcome, we extracted all outcomes of interest from that study; therefore, there are multiple instances of studies being included for an outcome even though the study might not have met study size criteria for that specific outcome.
- English language publications
- Peer reviewed publications

## Study Selection

All citations found by literature searches or through other sources were independently screened by two researchers. Upon the start of citation screening, we implemented a training session where all researchers screen the same articles and conflicts were discussed. We iteratively continue training until we have reached agreement regarding the nuances of the
eligibility criteria for screening. During double-screening, we resolved conflicts as a group. All screening of literature citations was done in the open-source, online software Abstrackr (http://abstrackr.cebm.brown.edu/).

All potentially eligible abstracts (regardless of source) were entered into an "evidence map". From each abstract, a single researcher extracted data on the study sample size (total), study design, study duration, the population category (healthy, at risk, CVD), the specific n-3 FA analyzed, whether biomarkers were reported, whether subgroup or factorial analyses were reported, and the outcomes mentioned in the abstract.

Based on the study descriptions in the evidence map, we selected the largest studies and those with subgroup or factorial analyses for full text review, with the goals of including a minimum of about 25 RCTs for each of the BP and plasma lipid outcomes, all RCTs with clinical outcomes, and a minimum of about 10 observational studies for each broad clinical outcome and also for dietary marine oils, dietary ALA, marine oil biomarkers, and ALA biomarkers.

## Data Extraction

Each study was extracted by one methodologist. The extraction was reviewed and confirmed by at least one other experienced methodologist. Disagreements were resolved by discussion among the team, with the team leader, or between extractors. Data were extracted into customized forms in Systematic Review Data Repository (SRDR) online system (http://srdr.ahrq.gov) and Excel spreadsheets, each designed to capture all elements relevant to the Key Questions. Upon completion of the review, the Excel spreadsheets (of observational study results data) were uploaded into SRDR and the database has made accessible to the general public (with capacity to read, download, and comment on data) (at http://srdr.ahrq.gov/). The basic elements and design of these forms include elements that address population characteristics; descriptions of the interventions, exposures, or biomarker status (and comparators) analyzed; outcome definitions; enrolled and analyzed sample sizes; study design features; results; and risk of bias assessment. The form was developed off the forms used for the original review. We also included questions pertinent to issues related to causality. We tested the forms on several studies and revised them as necessary before full data extraction.

## Quality (Risk of Bias) Assessment of Individual Studies

We assessed the methodological quality of each study based on predefined criteria. For RCTs, we used the Cochrane risk of bias tool, ${ }^{41}$ which asks about risk of selection bias, performance bias, detection bias, attrition bias, reporting bias, and other potential biases. For observational studies, we used relevant questions from the Newcastle Ottawa Scale. ${ }^{42}$ Additionally we included nutrition study specific risk of bias questions (e.g., related to uncertainty of dietary assessment measurements. ${ }^{13,15,43}$ Any quality issues pertinent to specific outcomes within a study were noted and applied to those outcomes. Any quality issues pertinent to specific outcomes within a study were noted and considered when determining the overall strength of evidence for conclusions related to those outcomes.

## Data Synthesis

All included studies were summarized in narrative form and in summary tables that tabulate the important features of the study populations, design, intervention, outcomes, and results. Other study data are in Appendix tables.

We analyzed different study designs separately and compared and contrasted populations, exposures, and results across study designs. We examined any differences in findings between observational and intervention studies, and evaluated the risk of bias factors as possible explanations for any heterogeneity.

Statistical analyses were conducted in Stata version 13.1 (StataCorp, College Station, Texas). We conducted random effects model meta-analyses of comparative studies (i.e., RCTs) if, for each set of studies with the same outcome and intervention and comparator pair, there were at least six studies. We used the restricted maximum likelihood method (with the metareg command) to calculate the overall and population-specific (healthy, at risk, CVD) effect sizes. For trials that compared multiple n-3 FA doses to placebo, we included only the comparison of the highest dose of n-3 FA versus placebo in meta-analysis. Likewise, for trials that compared both purified EPA and DHA to placebo, we arbitrarily included only the EPA versus placebo comparison.

We summarized included observational studies both qualitatively and quantitatively. We looked at hazard ratios (HR) and their respective confidence intervals of categorical outcomes of interest for each quantile of n-3 FA exposure (intake or biomarker level) within a study versus its reference quantile. The HRs were plotted at the median dose within a quantile's dose range (see below). Separate graphs were drawn for each combination of specific n-3 FA, measure type (e.g., intake, phospholipid level, percent FA), and outcome. We combined analyses of EPA+DHA and EPA + DHA+DPA. Within each graph, we plotted each reported cohort (i.e., from a given study, we plotted the analysis of the total cohort if that was reported, or we plotted both subgroup analyses-usually men and women-if only those were reported). We use unique symbols across graphs for all adults, men, women, and other subgroups.

When a study did not report the median doses for specific dose quantiles, we estimated them using the following rules. If the study provided the minimum and maximum dose within a quantile, we used the midpoint as the median dose. For the lowest and highest quantiles, if only one end of the range was reported (e.g., lowest quintile was $<0.5 \mathrm{~g} / \mathrm{d}$ ), we estimated the median dose to be $20 \%$ less (or more) than that quantile's upper (or lower) range. ${ }^{44}$ For studies that did not report the number of participants or person-years per quantile, we equally divided the total for the whole cohort to estimate the numbers per quantile.

We meta-analyzed multivariate observational cohorts when at least four cohorts analyzed the same n-3 FA, measure, and outcome. For each study cohort to be meta-analyzed, we used the STATA glst command to retrieve a set of coefficients and covariance matrices from generalized least squares trend estimation of splines with one knot each (exposure dose where the curve slope is allowed to change) across a range of knot points. Separately for ALA intake and EPA + DHA $\pm$ DPA intake (the n-3 FA measured that had sufficient data for meta-analysis), we determined the range of knots for spline models by ordering the median values of all quantiles of all ALA or all EPA + DHA $\pm$ DPA intake analyses being meta-analyzed (across outcomes) and selected a range from approximately the $5^{\text {th }}$ lowest to $5^{\text {th }}$ highest median values. Knot points were rounded to the nearest $0.1 \mathrm{~g} / \mathrm{d}$ and stepped up in $0.1 \mathrm{~g} / \mathrm{d}$ units to the highest knot point. We used the STATA glst command (generalized least squares) to estimate the splines for each cohort being meta-analyzed, across the range of knots. For a particular cohort, if a knot fell outside the
cohort's n-3 FA dose range, we generated a linear model without a knot. We then used the STATA mvmeta command to meta-analyze these spline models (at each knot). We captured the Akaike information criterion (AIC) for each meta-analyzed spline (at each knot). We tabulated all meta-analyzed spline models for each set of studies (within a range of knots that pertain to each set of studies). In the figures of the association of n-3 FA exposure versus risk of outcome, we included the meta-analysis spline with the best fit (the lowest AIC value).

## Summary of Causality-Related Study Features

We compiled a pair of appendix tables (Appendix G) with data related to possible causality criteria. The list of items in this table was compiled based on discussions between the EPCs and ODS after discussion of the Bradford Hill criteria ${ }^{37}$ and other issues related to determining causality. The table includes a listing of included studies with their population category (healthy, at high CVD risk, with CVD), CVD risk type (e.g., diabetes, hypertension, chronic kidney disease, dyslipidemia), demographics (age, sex, race), CVD history, CVD risk factors (BP, plasma lipids, weight), baseline n-3 FA intake, n-3 FA source, n-3 FA type, how n-3 FA intake measured, study design (e.g., RCT, prospective or retrospective longitudinal cohort, or other design), exposure duration, followup duration, outcomes reported, whether outcomes were reported to be primary outcomes (vs. secondary), effect sizes, difference in n-3 FA intake (between low and high intake groups), and a dose-corrected effect size. The determination of primary outcomes was based on an explicit statement of the primary outcomes, the outcome used in reported power calculations, or if implied by focus of the original article. In addition, if the study was found in a registry and its primary outcome in this database differed from the stated primary outcome in the article, this information was included. The dose-corrected effect size is the effect size divided by the daily dose of tested n-3 FA.

## Strength of the Body of Evidence

We graded the strength of the body of evidence as per the AHRQ Methods Guide on assessing the strength of evidence for each outcome. ${ }^{45}$ Following the standard AHRQ approach, for each intervention and comparison of intervention, and for each outcome, we assessed the number of studies, their study designs, the study limitations (i.e., risk of bias and overall methodological quality), the directness of the evidence to the Key Questions, the consistency of study results, the precision of any estimates of effect, the likelihood of reporting bias, and the overall findings across studies. Based on these assessments, we assigned the strength of evidence rating as being either high, moderate, or low, or there being insufficient evidence to estimate an effect.

We assigned "High" strength of evidence only if there were sufficient, consistent, precise RCTs without limitations and any association studies yielded similar conclusions. Without such RCT evidence, the highest possible strength of evidence was "Moderate".

For outcomes with $\leq 2$ RCTs providing evidence, the highest possible strength of evidence was "Low" under the presumption that observational studies (that analyzed the association between a one-time estimate of n-3 FA status and clinical outcomes $\geq 1$ year in the future) cannot alone provide good evidence of an effect of n-3 FA intake. For outcomes with $\leq 2$ RCTs, $\leq 2$ observational studies of intake, and $\leq 2$ observational studies of biomarkers, the strength of evidence grade was "Insufficient." Where RCTs and observational studies yielded different conclusions about significance of effect/association, we assigned a low strength of evidence of the conclusion of the RCTs. For example, if RCTs found no significant effect, but
observational studies found a significant association, we concluded low strength of evidence of no effect. If we were unable to conclude a finding of an association or effect, or no association or effect, (generally because of imprecision or inconsistency across studies), we determined that the evidence was "Insufficient" since it is not meaningful to state that there is a low strength of evidence of an unclear effect/association.

The strength-of-evidence dimensional rating are summarized in Evidence Profile tables detailing our reasoning for arriving at the overall strength of evidence rating. Study characteristics related to causality are tabulated in Appendixes G. 1 and G.2.

## Applicability

We assessed the applicability within and across studies with reference to whether people in the studies were in the three populations of interest (healthy, at risk, and with CVD), and as pertains to n-3 FA source, type, and dose/exposure.

## Peer Review and Public Commentary

A draft version of this report was reviewed by a panel of expert reviewers and the general public. The reviewers were either directly invited by the EPC or offered comments through a public review process. Revisions of the draft were made, where appropriate, based on their comments. The draft and final reports were also reviewed by the Task Order Officer and an Associate Editor from another EPC. However, the findings and conclusions are those of the authors, who are responsible for the contents of the report.

## Results

The Results chapter is organized as follows. The chapter starts with an overall description of the included studies and their risk of bias assessment. The bulk of the chapter is organized by outcome, with a description first of the randomized controlled trials (RCT) and their subgroup analyses, followed by the observational studies and their subgroup analyses. Within each description of studies, we follow the basic pattern of first describing the evidence regarding total omega-3 fatty acids (n-3 FA) combined, then alphalinolenic acid (ALA), the individual longchain n-3 FA (eicosapentaenoic acid [EPA], docosahexaenoic acid [DHA], docosapentaenoic acid [DPA], and stearidonic acid [SDA]), and then combined long-chain n-3 FA ( $\mathrm{EPA}+\mathrm{DHA} \pm \mathrm{DPA}$ ). Within the description of the observational studies, we first present the results of associations with n-3 FA intake followed by n-3 FA biomarkers.

Appendix A presents the literature search strategies. Appendix B lists the articles that were reviewed in full text that were excluded, with their rejection reasons. Appendix C presents the study-level risk of bias assessments of all studies. Appendix D presents study-level baseline data. Appendix E presents study-level design features. Appendix F presents the study-level results data for the observational studies. Appendix G presents the "causality tables" described in the Methods section.

## Summary of Studies

The literature searches yielded 11,440 citations (Figure 3). Reference lists from existing systematic reviews yielded 203 additional citations (which mostly represented articles published before 2002). Of these, 829 abstracts met basic eligibility criteria. As described in the Methods chapter (under Study selection), using an evidence map process, we selected 463 articles for full text review, of which 147 articles met eligibility criteria, representing 61 RCTs (in 82 articles) and 37 longitudinal observational studies (in 65 articles). ${ }^{46-192}$

## Study Risk of Bias

Across RCTs, the studies generally had few risk of bias concerns (Figure 4, Appendix C). Among the 61 RCTs, 23 (38\%) had no high risk of bias / study quality limitations; an additional 26 RCTs (43\%) had one risk of bias limitation and 6 (10\%) had two risk of bias limitations. None of the remaining 6 RCTs (10\%) had more than four study limitations (of 10 explicitly assessed potential limitations). The most common risk of bias limitation was a lack of intention-to-treat analyses; 12 RCTs (20\%) clearly did not conduct intention-to-treat analyses (one of these conducted an intention-to-treat analysis for the outcome death, but not for lipid outcomes); 12
additional RCTs (20\%) were unclear whether intention-to-treat analyses were conducted. Ten RCTs (16\%) did not blind study participants (and 4 additional, 7\%, were unclear whether they blinded participants), often because the intervention was dietary and could not be blinded. However, only 7 RCTs (11\%) clearly did not blind outcome assessors (nine additional RCTs, $14 \%$, were unclear regarding outcome assessor blinding). Attrition bias, primarily due to dropout rates greater than 20 percent, was present in 9 RCTs (15\%). Other potential biases were less common.

Figure 4. Risk of bias of randomized controlled trials

Risk of bias, by specific question, of the 61 included randomized controlled trials. See Appendix C for details.
Across the observational studies, there were fairly few risk of bias concerns (Figure 5). Nine of 37 studies (24\%) had no high risk of bias concerns; 20 (54\%) had only a single high risk of bias concern (of 7 explicitly assessed potential limitations) and 6 (16\%) had two risk of bias concerns. The 2 remaining studies (5\%) had three risk of bias concerns. No study was deemed to have high risk of selection bias (regarding whether the outcome was present at baseline) and all adequately adjusted for confounders. The majority of studies used a dietary assessment tool that did not include dietary supplements (18 of 29 applicable studies; 62\%); an additional 4 studies (14\%) were unclear whether dietary supplements were used. Sixteen studies (43\%) did not adequately reported baseline nutrient exposures. Bias due to lack of outcome assessor blinding was infrequent (3 studies [8\%]; 4 studies [11\%] were unclear), as was attrition bias (1 study [3\%]; 4 studies [11\%] were unclear). All observational studies reported multivariate analyses (this was an eligibility criterion).

Figure 5. Risk of bias of longitudinal, prospective observational studies

Risk of bias, by specific question, of the 37 included longitudinal observational studies. For dietary assessment, studies rated high risk of bias if only diet (not supplements) were included in the food frequency questionnaire; studies that evaluate only biomarkers were not evaluated for risk of bias for dietary assessment (not applicable). See Appendix C for details.

Abbreviations: n-3 FA = omega-3 fatty acids.
Tables 1 and 2 enumerate studies by n-3 FA, strength of evidence, and overall effect or association by outcome (clinical and intermediate separately). The table highlights the lack of sufficient evidence for most clinical cardiovascular disease (CVD) outcomes (empty cells and unshaded cells with black font). Only for marine oil (EPA+DHA) is there sufficient evidence for beneficial effect (or association) of higher n-3 FA intake. The body of evidence provides no sufficient evidence of a significant effect (or association) of ALA on CVD outcomes or examined risk factors.

## Major Adverse Cardiovascular Events

## Randomized Controlled Trials

Ten RCTs reported the composite outcome major adverse cardiac event (MACE) (Table 3). ${ }^{67,90,96,115,119,121,123,146,157,160}$ Of these, three studies were conducted in a total of 31,713 people at risk of CVD including dyslipidemia, ${ }^{90,115}$ or a combination of various risk factors. ${ }^{160}$ Eight studies were conducted in a total of 35,095 people with CVD, defined as a history of CVD, ${ }^{123}$ a history of myocardial infarction (MI), ${ }^{67,119,121}$ acute MI, ${ }^{90}$ previous coronary heart disease (CHD), ${ }^{90}$ peripheral artery disease at any time, ${ }^{90}$ persistent atrial fibrillation (AFib), ${ }^{157}$ heart failure, ${ }^{96}$ or, in one study, either a history of CVD or of diabetes. ${ }^{146}$ None of the RCTs were conducted in a generally healthy population. One study analyzed MACE as a primary outcome (Roncaglioni 2013); however, the trial changed the primary outcome at 1 year from CVD death due to a low event rate. ${ }^{160}$

MACE was defined differently for each study, but was generally a composite of all-cause death, ${ }^{96,121,157}$ cardiovascular (CV) death, ${ }^{123,146,160}$ cardiac death, ${ }^{67,90}$ fatal and nonfatal MI, ${ }^{67,90,}$ 115, 119, 123,146 cardiac arrest, ${ }^{115,119}$ unstable angina, ${ }^{67,90}$ hospitalization for CV reasons, ${ }^{96,157,160}$ ${ }_{121}^{\text {stroke, }}{ }^{115,119,121,123,146}$ coronary artery bypass grafting, ${ }^{90,115}$ and/or other CV procedures. ${ }^{67,90,115,}$ 121

## Marine Oil Versus Placebo

Meta-analysis of the 10 RCTs of marine oil versus placebo yielded a nonsignificant summary effect size for risk of MACE: hazard ratio $(\mathrm{HR})=0.96$ ( $95 \%$ confidence interval [CI] 0.91 to 1.02 ) (Figure 6). ${ }^{67,90,96, ~ 115, ~ 119, ~ 121, ~ 123, ~ 146, ~ 160, ~} 166$

## At-Risk-for-CVD Population

Among people at risk of CVD, one trial compared EPA ethyl ester (combined with statin) with control (statin alone) in 18,645 participants with dyslipidemia ( $19.5 \%$ with CHD) ${ }^{90}$ and two studies compared marine oil (EPA+DHA) to placebo (olive oil or corn oil) in a total of 13,068 participants with dyslipidemia or multiple CVD risk factors. ${ }^{115,160}$ In the study of EPA ethyl ester, the dose of EPA was $1.8 \mathrm{~g} / \mathrm{d}$; in the other two studies the doses of EPA+DHA were 0.85 and $2.02 \mathrm{~g} / \mathrm{d}$ with EPA to DHA ratio either 0.9 or 1.5 . Compliance was monitored and the adherence level was greater than 90 percent in one study, ${ }^{115}$ but not reported in the other two studies. The duration of followup ranged from 3 to 5 years.

In one RCT, EPA supplementation ( $1.8 \mathrm{~g} / \mathrm{d}$ ) had a significant additive effect (to statin therapy) on reducing the risk of MACE (including sudden cardiac death [SCD], fatal and nonfatal MI, and nonfatal unstable angina pectoris, angioplasty, stenting, or coronary artery bypass grafting) compared with statin alone after 5 years of followup, both when including the 19.5 percent of patients with CHD (HR 0.81; 95\% CI 0.69 to 0.95 ) and when considering the subpopulation with dyslipidemia only (HR 0.81 ; 95\% CI 0.66 to 1.00 )..$^{90}$ The other two trials found that EPA+DHA supplementation ( 0.85 and $2.02 \mathrm{~g} / \mathrm{d}$ ) did not significantly reduce the risk of MACE (heterogeneous definitions) compared with placebo (HR 0.98, 95\% CI 0.88 to 1.08; HR $0.89,95 \%$ CI 0.55 to 1.44 )

Subgroup meta-analysis yielded a summary HR of 0.90 ( $95 \%$ CI 0.77 to 1.05 ) for people at risk for CVD.

## CVD Population

Among people with CVD, eight RCTs (seven parallel design, one a 2-by-2 factorial RCT) evaluated MACE. Six simple RCTs compared marine oil (EPA+DHA) to placebo (olive oil in two studies and sources not reported in the other two studies) in a total of 22,259 participants with diabetes and history of CVD, all CVD, heart failure or previous persistent AFib. ${ }^{96,123,146,157}$ The 2-by-2 factorial RCT compared the effects of a margarine supplemented with EPA + DHA alone ( $0.4 \mathrm{~g} / \mathrm{d}$ ), a combination of both EPA+DHA and ALA margarines, and ALA alone ( $2 \mathrm{~g} / \mathrm{d}$ ) with placebo margarine (oleic acid) in 4837 participants with a history of MI. ${ }^{119}$ (The 2-by-2 factorial trial reported only analyses of EPA+DHA vs. placebo and ALA vs. placebo.) One trial compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester plus statin with statin alone in two populations: 3,664 with previous CHD and 223 with peripheral artery disease at any time. ${ }^{90}$

Among the seven trials that compared marine oil (EPA+DHA) to placebo, the doses of EPA+DHA used ranged from 0.4 to $3.5 \mathrm{~g} / \mathrm{d}$, and the EPA to DHA ratio ranged from 0.5 to 2 . Reported in five studies, the compliance ranged from 70 to 90 percent. The duration of followup ranged from 1 to $>6$ years. Six of the seven trials found that EPA+DHA supplementation did not significantly reduce the risk of MACE (heterogeneous definitions) compared with placebo (HR or odds ratio [OR] ranging from 0.88 to 1.21). ${ }^{67,119,121,123,146,157}$ The seventh trial found that EPA + DHA ethyl ester supplementation significantly reduced the risk of MACE (defined as death from any cause or admission to the hospital for CV reasons) compared with placebo in 6975 participants with heart failure (HR 0.92, 95\% CI 0.85 to 0.99 ). ${ }^{96}$ In the trial that compared EPA plus statin with statin alone, the analysis of patients with previous CHD found no significant additive effect of EPA supplementation on the risk of MACE (HR 0.82; 95\% CI 0.63 to 1.06), while the analysis of patients with peripheral artery disease at any time did find a significant additive effect (HR 0.44; 95\% CI 0.19 to 0.97 ). ${ }^{90}$

Subgroup meta-analysis yielded a summary HR of 0.98 ( $95 \%$ CI 0.92 to 1.05) for people with CVD.

## ALA Versus Placebo

## CVD Population

In the 2-by-2 factorial RCT, the groups that received ALA margarines had no significant difference in the risk of MACE compared with placebo margarines (HR 0.92; 95\% CI 0.73 to 1.11). ${ }^{119}$

## RCT Subgroup Analyses

Three RCTs reported subgroup analysis for MACE (Table 4). In one trial, EPA+DHA (vs. placebo) lowered the risk of MACE in women ( $\mathrm{HR}=0.82$ ) in contrast with the effect in men (HR 1.04) and the difference between women and men was statistically significant ( P interaction 0.04). ${ }^{160}$ The second trial found no difference in effect of EPA versus placebo between men and women (HR 0.76 vs 0.87 , P-interaction 0.43 ). ${ }^{90}$ This study analyzed several other subgroups, but found no significant differences in effect between any subgroups. These included age $\geq 61$ versus $<61$ years, body mass index $\geq 24$ versus $<24 \mathrm{~kg} / \mathrm{m}^{2}$, triglycerides ( Tg ) $\geq 270$ versus $<270 \mathrm{mg} / \mathrm{dL}$, $\mathrm{Tg} \geq 150$ versus $<150 \mathrm{mg} / \mathrm{dL}$, high density lipoprotein cholesterol (HDL-c) $\geq 58$ versus $<58$ $\mathrm{mg} / \mathrm{dL}$, low density lipoprotein cholesterol (LDL-c) $\geq 181$ versus $<181 \mathrm{mg} / \mathrm{dL}$, history of CHD versus no CHD, smoker versus nonsmoker, diabetes versus no diabetes, and hypertension versus no hypertension. ${ }^{90}$ The third trial reported an incomplete and unclear analysis of many subgroup
analyses for both EPA+DHA versus placebo and ALA versus placebo. No interaction analyses were reported, but near-significant effects ( $\mathrm{P}<0.10$ ) of ALA on MACE reduction were seen for those $<70$ years old (HR $0.83, \mathrm{P}=0.08$ ) as opposed to older subjects (HR 1.00, $\mathrm{P}=0.98$ ) and for women (HR 0.73, $\mathrm{P}=0.07$ ) as opposed to men (HR $0.96, \mathrm{P}=0.60$ ). No significant effects of ALA were found in all subgroups based on time since MI, baseline fish intake, baseline EPA+DHA intake, and history of diabetes. No significant effects of EPA+DHA were found in all subgroups analyzed.

Meta-regression of the marine oil trials found no significant interaction between n-3 FA dose ( $\mathrm{P}=0.15$ ), followup time $(\mathrm{P}=0.49)$, or between at risk and CVD populations $(\mathrm{P}=0.63)$

## Observational Studies

Seven studies evaluated variously defined MACE (or total CVD events), composite outcomes that combined cardiac, coronary, and cerebrovascular events (Appendix F, Major adverse cardiac events section; Figure 7). Each study used its own combination of diagnoses. The studies included generally healthy adults or, in one instance, "at risk" adults with hypercholesterolemia on low dose statins. ${ }^{50,101,122,126,137,155, ~ 171,183}$ Followup durations ranged from 4 to about 20 years.

## n-3 FA Intake

Five studies evaluated n-3 FA intake (Danish National Birth Cohort, Health Professional Follow-up Study, Malmo Diet and Cancer, MESA, Physician's Health Study). ${ }^{50,101, ~ 137, ~ 155, ~ 171, ~ 183 ~}$

Three studies analyzed intake of total n-3 FA combined (Figure 7, plot \# 17 \& 18). The Physician's Health Study (in healthy men) ${ }^{50,155}$ and the Malmo Diet and Cancer study (in healthy adults) ${ }^{183}$ both found no association with MACE at 4 and 14 years of followup. In contrast the Danish National Birth Cohort (in healthy women who were pregnant at the time of enrollment) found significantly increased risks of cerebrovascular, ischemic heart disease, or hypertensive disease hospitalization after 12 years on those with higher n-3 FA intake (Figure 7, plot \#18). ${ }^{137}$ However, no clear intake threshold was found.

The Malmo Diet and Cancer and MESA studies found no association between ALA intake and MACE at 10 and 14 years of followup (Figure 7, plots \#1 \& 2). ${ }^{171,183}$

MESA found an overall significant association between both EPA, DHA, and DPA intake (separately) and combined ischemic coronary events, cardiac arrest, stroke, and CVD death in healthy adults after 10 years of followup (Figure 7, plots \#4, 8, 14). ${ }^{171}$ For DHA intake, the association was near-significant $(\mathrm{P}<0.10)$ for the uppermost quartile with a median dose of $0.15 \mathrm{~g} / \mathrm{d}$, for DPA $0.02 \mathrm{~g} / \mathrm{d}$, and for EPA $0.04 \mathrm{~g} / \mathrm{d}$.

Three studies evaluated combined EPA+DHA or EPA+DHA+DPA intake (Figure 7, plots \# 11 \& 12). The Health Professionals Follow-up Study (evaluating EPA+DHA) ${ }^{101}$ and Malmo Diet and Cancer study (evaluating EPA+DHA+DPA) ${ }^{183}$ found no significant association at 14 and 18 years of followup. MESA found an overall statistically-significant lower risk of combined ischemic coronary events, cardiac arrest, stroke, and CVD death in healthy adults after 10 years of followup with higher intake of EPA+DHA+DPA. ${ }^{171}$ The association was nearsignificant for the highest quartile with a median intake dose of about $0.3 \mathrm{~g} / \mathrm{d}(\mathrm{P}<0.10)$.

## n-3 FA Biomarkers

Five studies evaluated n-3 FA biomarkers (JELIS, Physician’s Health Study, Scottish Heart Health Extended Cohort Study, MESA, Hisayama). ${ }^{50,122,126,155,168,171}$

The Physician's Health Study and MESA found no associations between erythrocyte or phospholipid ALA levels and MACE (Figure 7, plot \# 3, erythrocyte n-3 FA associations not plotted because they were not analyzed by quantile). ${ }^{50,155,171}$

Four studies evaluated EPA biomarkers, two of which found statistically significant associations with MACE (Figure 7, plots \#10 \& 16). The Physician's Health Study found no significant association between erythrocyte EPA and MACE in healthy men. ${ }^{50,155}$ Hisayama found no significant association between plasma EPA and MACE in healthy patients. ${ }^{168}$ MESA, in contrast, found a significant association between higher phospholipid EPA and lower MACE (Figure 7, plot \#15). ${ }^{171}$ In a population of people with dyslipidemia on low-dose statins, JELIS also found a significant association between higher plasma EPA and lower risk of MACE (Figure 7, plot \#10). ${ }^{122}$

Five studies evaluated DHA biomarkers, with heterogeneous findings (Figure 7, plots \#6 and 7; other biomarkers not plotted due to insufficient reported data or not quantile analysis). Hisayama, JELIS and the Physician's Health Study found no significant associations with plasma or erythrocyte DHA. ${ }^{50,122,155,168}$ The Scottish Heart Health Extended Cohort Study, though, found that higher adipose tissue DHA levels were associated with reduced risk of MACE at about 20 years of followup, ${ }^{126}$ and the MESA study also found reduced risk of MACE associated with higher phospholipid DHA levels at 10 years of followup. ${ }^{171}$

Three studies evaluated DPA biomarkers, one of which found a significant association (Figure 7, plot \#9; other biomarkers not plotted due to insufficient reported data or not quantile analysis). The Scottish Heart Health Extended Cohort Study found that higher adipose tissue DPA levels were associated with lower risk of MACE at about 20 years of followup. ${ }^{126}$ In contrast, the Physician's Health Study and MESA found no significant associations with erythrocyte or phospholipid DPA. ${ }^{50,155,171}$

The Physician's Health Study also found no significant association between erythrocyte SDA and MACE. ${ }^{50,155}$

Two studies evaluated combined EPA+DHA biomarkers (Figure 7, plot \#13). The Physician's Health Study found no association with erythrocyte EPA+DHA, ${ }^{50,155}$ but MESA found that higher phospholipid EPA+DHA levels were associated with lower risk of MACE at 10 years of followup. ${ }^{171}$

## Observational Study Subgroup Analyses

Only MESA reported subgroup analyses. ${ }^{171}$ In comparisons of n-3 FA biomarker associations with MACE by race, the study found no significant differences in associations for EPA, DHA, and EPA+DHA+DPA levels, but whites ( $\mathrm{HR}=0.41$ ) and Chinese ( $\mathrm{HR}=0.30$ ) had significantly stronger associations than African Americans (HR=1.51) and Hispanics (HR=1.33; P interaction $=0.01$ ).

Abbreviations: ALA = alphalinolenic acid, CHD = coronary heart disease, CVD = cardiovascular disease, DHA = docosahexaenoic acid, EPA = eicosapentaenoic acid, HDL-c = high density lipoprotein cholesterol, $\mathrm{HR}=$ hazard ratio, $\mathrm{HTN}=$ hypertension, $\mathrm{LDL}-\mathrm{c}=$ low density lipoprotein cholesterol, $\mathrm{MI}=$ myocardial infarction, $\mathrm{n}-3 \mathrm{FA}=$ omega-3 fatty acids, $\mathrm{NS}=$ not significant, $\mathrm{PAD}=$ peripheral artery disease, $\mathrm{Tg}=$ triglycerides.

Figure 6. Major adverse cardiovascular events: Randomized trials of marine oils

Random effects model meta-analysis of n-3 FA versus placebo (or no n-3 FA), with subgroup analyses by population. In all meta-analyses, only studies that reported sufficient results data are included.

Abbreviations: $\mathrm{CI}=$ confidence interval, CVD = cardiovascular disease, $\mathrm{DHA}=$ docosahexaenoic acid, EPA $=$ eicosapentaenoic acid, $\mathrm{FA}=\mathrm{fatty}$ acid(s), $\mathrm{n} / \mathrm{N}=$ number with outcome/number analyzed, n-3 FA = omega-3 fatty acids, Phet $=\mathrm{P}$ value of chi-squared test of heterogeneity across studies, PMID $=\mathrm{PubMed}$ Identification number.

Figure 7. n-3 FA associations with major adverse cardiovascular events: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted. $P$ values are the study-reported $P$ value for the trend across quantiles. Where $95 \%$ confidence intervals (vertical lines) are missing, these were not reported in the studies.
White triangles = healthy adults, black circles = adults with dyslipidemia (at risk), white squares = healthy males, black squares $=$ healthy females.

Abbreviations: $\mathrm{AA}=$ arachidonic acid, ALA $=$ alphalinolenic acid, DHA $=$ docosahexaenoic acid, DPA $=$ docosapentaenoic acid, EPA = eicosapentaenoic acid, HR = hazard ratio, n-3 FA= omega-3 fatty acids.

## CVD Death (Including Stroke)

## Randomized Controlled Trials

Seven RCTs reported total CVD death (Table 5). ${ }^{67,70,96,115,119,146,160}$ Of these, two were conducted in a total of 13,068 people at risk of CVD defined as dyslipidemia or at least four CVD risk factors, ${ }^{115,160}$ and the other five in a total of 36,002 people with CVD including diabetes, history of CVD, MI or heart failure. ${ }^{67,70,96,119,146}$ None of the trials analyzed CVD death as a primary outcome, but Roncaglioni 2013 reported that it was the a priori primary outcome; the primary outcome was changed to MACE at 1 year due to a low event rate for CVD death). ${ }^{160}$

## Marine Oil Versus Placebo

Meta-analysis of the seven RCTs of marine oil versus placebo yielded a nonsignificant summary effect size for risk of CVD death: HR=0.92 (95\% CI 0.82 to 1.02) (Figure 8). ${ }^{67,70,96,}$ 115, 119, 146, 160

## At-Risk-for-CVD Population

Among people at risk of CVD, two studies compared marine oil (EPA + DHA) to placebo (either olive oil or corn oil) in a total of 13,068 participants. ${ }^{115,160}$ The doses of EPA and DHA were less than 0.85 and $2.02 \mathrm{~g} / \mathrm{d}$, and the EPA to DHA ratio ranged from 0.9 to 1.5 . Compliance was high ( $>90 \%$ ) in one study ${ }^{115}$ and not reported (although monitored by self-report) in another study. ${ }^{160}$ The durations of followup were 3 and 5 years. Both studies found that EPA+DHA supplementation did not significantly reduce CVD death compared with placebo (HR 1.03, 95\% 0.82 to 1.30 ; OR 0.62 , $95 \%$ CI 0.24 to 1.64 ).

Subgroup meta-analysis yielded a summary HR of 0.99 ( $95 \%$ CI 0.77 to 1.28) for people at risk for CVD.

## CVD Population

Among people with CVD, five trials compared marine oil (EPA+DHA) to placebo (olive oil in one study, corn oil in another, and source was not reported in one study), ${ }^{67,96,146}$ to no intervention, ${ }^{70}$ and in a factorial study with ALA, ${ }^{119}$ in a total of 36,002 participants. The dose of EPA+DHA ranged from 0.84 to $3.5 \mathrm{~g} / \mathrm{d}$, and the EPA to DHA ratio ranged from 0.5 to 1.24. Compliance ranged from about 70 to 88 percent. The mean duration of followup ranged from 2.4 to more than 6 years. Two of the five studies found that EPA+DHA supplementation significantly reduced the CVD death compared with no intervention or placebo in 11,334 participants with MI (RR $0.70,95 \%$ CI 0.56 to 0.86$)^{70}$ and in 6975 participants with heart failure (adjusted HR $0.91,95 \%$ CI 0.81 to 0.99 ). ${ }^{96}$ Two studies did not find a difference in the risk of CVD death between EPA+DHA and placebo in 12,536 participants with diabetes or history of

CVD (HR 0.98, 95\% CI 0.87 to 1.10 ). ${ }^{146}$ and in 300 participants with acute MI (HR 1.37, $95 \%$ CI: 0.63 to 3.01 ). ${ }^{67}$ The fifth study was the 2-by- 2 factorial RCT described under Major Adverse CVD Events that compared EPA+DHA, EPA + DHA and ALA, ALA, and oleic acid margarines in 4837 participants with MI. ${ }^{119}$. During a mean of 3.4 years of followup, EPA+DHA containing margarines had no significant effect on CVD death compared with the ALA alone or placebo margarines (HR 0.98; 95\% CI 0.72 to 1.33).

Subgroup meta-analysis yielded a summary HR of 0.90 ( $95 \%$ CI 0.79 to 1.03) for people with CVD.

## ALA Versus Placebo

## CVD Population

In the 2-by-2 factorial RCT, the groups that received ALA margarines had no significant difference in the risk of MACE compared with placebo margarines (HR 0.94; 95\% CI 0.69 to 1.27). ${ }^{19}$

## RCT Subgroup Analyses

Three RCTs reported subgroup analysis for CVD death (Table 6). The same 2-by-2 factorial RCT analyzed subgroups based on history of diabetes. ${ }^{119}$ For patients with diabetes, EPA+DHA had a nonsignificant reduction in CVD death risk ( $\mathrm{HR}=0.60, \mathrm{P}=0.08$ ) in contrast to those without diabetes ( $\mathrm{HR}=1.21, \mathrm{P}=0.32$ ); no test for interaction was reported. The effect of ALA on CVD death was similarly nonsignificant in both patients with diabetes ( $\mathrm{HR}=0.87$, $\mathrm{P}=0.63$ ) and those without diabetes ( $\mathrm{HR}=0.97, \mathrm{P}=0.87$ ).

Bosch 2012 analyzed subgroups based on glargine use, age over 65, prior CVD events, heart rate over 69 beats per minute, statin use, beta blocker use, tertiles of n-3 FA intake, and triglyceride tertiles, none of which found significant interactions or significant effects of EPA + DHA on CVD death.

Meta-regression of the marine oil trials found no significant interaction between n-3 FA dose ( $\mathrm{P}=0.59$ ), followup time $(\mathrm{P}=0.33)$, or between at risk and CVD populations $(\mathrm{P}=0.75)$

## Observational Studies

Eight studies evaluated the association between n-3 FA intake or biomarkers and total CVD death in healthy adults from 4 to 31 years of followup (median 11 years) (Appendix F Death from cardiovascular disease section; Figure 9). ${ }^{47,50,72,95,98,159,162,175,186}$ The studies had heterogeneous findings regarding associations between higher n-3 FA intake or biomarker levels and lower risk of CVD death.

## n-3 FA Intake

Eight studies evaluated n-3 FA intake (JACC, MRFIT, NIPPON DATA80, Physician's Health Study, Shanghai Women's and Men's Health Studies, Singapore Chinese Healthy Study, Takayama, VITAL). ${ }^{47,50,72, ~ 98, ~ 155, ~ 162, ~ 170, ~ 175, ~} 176$

Four studies evaluated total n-3 FA intake (JACC, NIPPON DATA80, Physician’s Health Study, Singapore Chinese Health Study) (Figure 9, plots \#31 \& 32). ${ }^{50,988,155,170, ~ 175, ~ 176 ~}$ JACC found a significant association between higher total n-3 FA intake (combined) and lower CVD death risk in healthy adults after about 13 years of followup, with a significant association occurring in quantile with median of $2 \mathrm{~g} / \mathrm{d}$ or higher. ${ }^{98}$ JACC and NIPPON DATA80, however,
found no significant associations at 4 and 24 years of followup. ${ }^{98,175}$ The Singapore Chinese Health Study found no significant association between higher total n-3 FA intake and lower CVD death risk in CVD adults, but found a significant association in healthy adults ( $\mathrm{P}=0.006$ ). ${ }^{170}$

Three studies evaluated ALA intake with conflicting results (Figure 9, plots \#19 \& 20). MRFIT found a significant association between higher ALA intake (measured as percent Kcal) and lower CVD risk at about 10 years (particularly in quartiles with median intake greater than about $0.7 \% \mathrm{Kcal}$ ); when ALA intake was measured as $\mathrm{g} / \mathrm{d}$, the association was similar, but nonsignificant ( $\mathrm{P}=0.10$ ). The Cardiovascular Health Study found no association at 12 years of followup. ${ }^{47}$ The Singapore Chinese Health Study found no significant association between higher ALA intake and lower CVD death risk in CVD adults, but found a significant association in healthy adults ( $\mathrm{P}<0.001$ ) ${ }^{170}$

Two studies evaluated EPA intake, also with conflicting results (Figure 9, plots \#28 \& 29). NIPPON DATA80 found no association at 24 years of followup, ${ }^{175}$ but the Shanghai Women's and Men's Health Studies found a significant association between higher EPA intake and lower risk of CVD death among men (at about 6 years of followup) and women (at about 12 years), combined (with significant associations in all quintiles with median intake of about 0.01 $\mathrm{g} / \mathrm{d}$ or higher). ${ }^{162}$

The same two studies evaluated DHA intake (Figure 9, plots \#22 \& 23). NIPPON DATA found no significant association between higher DHA intake and lower CVD death risk ( $\mathrm{P}=0.099$ ). ${ }^{175}$ The Shanghai Women's and Men's Health Studies found a significant association between higher EPA intake and lower risk of CVD death, as with EPA. ${ }^{162}$ Significant or nearsignificant ( $\mathrm{P}<0.10$ ) associations were seen in quantiles with median doses of about 1.25 percent Kcal or about $0.02 \mathrm{~g} / \mathrm{d}$, or higher.

Six studies evaluated EPA+DHA intake (3 studies; NIPPON DATA80, Shanghai Women's and Men’s Health Studies, Singapore Chinese Health Study, Takayama, VITAL) ${ }^{72,162,}$ 170, 175, 176 or EPA+DHA+DPA intake (MRFIT) (Figure 9, plots \#26 \& 27). ${ }^{47}$ The Shanghai Women's and Men's Health Studies and MRFIT found significant associations between higher marine oil intake and lower CVD death risk. ${ }^{47,162}$ The Singapore Chinese Health Study found no significant association between higher marine oil intake and lower CVD death risk in CVD adults, but found a significant association in healthy adults ( $\mathrm{P}=0.002$ ). ${ }^{170}$ VITAL found no significant associations between higher marine oil intake and lower CVD death risk in both healthy and CVD adults. ${ }^{176}$ In MRFIT, the association was statistically significant when marine oil intake (either $\mathrm{g} / \mathrm{d}$ or $\% \mathrm{Kcal}$ ) was analyzed as a continuous variable in a linear model and near-significant ( $\mathrm{P}<0.10$ ) when analyzed across quintiles. ${ }^{47}$ Both NIPPON DATA80 and Takayama found no significant associations overall. ${ }^{72,175}$ For percent Kcal analyses, nearsignificant associations were found in quantiles with median intake of about 0.30 percent Kcal or higher. In two of the $\mathrm{g} / \mathrm{d}$ analyses, near-significant associations were found in quantiles with median marine oil intake of about $0.7 \mathrm{~g} / \mathrm{d}$.

By meta-analysis (Table 7), overall there is a statistically significant association between marine oil intake and CVD death across a median dose range of 0.066 to $1.58 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.88 ; 95 \%$ CI 0.82 to 0.95 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1). This implies the possibility of a ceiling effect (where intake above a certain level adds no further benefit). However, at no dose threshold was there a statistically significant difference between the ES below the dose threshold (knot) and above the
threshold. The best fit curve was found with a knot at $0.3 \mathrm{~g} / \mathrm{d}$. The lowest P value between lowerdose and higher-dose ES estimates was found at $0.2 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.26)$.

## n-3 FA Biomarkers

The Cardiovascular Health Study and ULSAM evaluated n-3 FA plasma levels. ${ }^{95}$, 148
The Cardiovascular Health Study found a significant association between higher total n-3 FA plasma levels and lower risk of CVD death (Figure 9, plot \#33). ${ }^{148}$

Both the Cardiovascular Health Study and ULSAM found no association between plasma ALA levels and CVD death risk (Figure 9, plot \# 21). ${ }^{95,148}$

For both plasma EPA and DHA levels (separately), the Cardiovascular Health Study found significant associations between higher plasma levels and lower risk of CVD death at 16 years of followup. ${ }^{148}$ In contrast, ULSAM found no significant association at about 31 years of followup (Figure 9, plots \#24 \& 30). ${ }^{95}$

The Cardiovascular Health Study also found a significant association between higher plasma DPA levels and lower risk of CVD death (Figure 9, plot \#25).

## Observational Study Subgroup Analyses

Only the Cardiovascular Health Study reported subgroup analyses. ${ }^{148}$ In their analysis of ALA intake, they reported no significant difference (without details) in association between participants with high, low, or no fish consumption and between men and women.

## Cardiac Death

## Randomized Controlled Trials

Five RCTs reported on cardiac death (combined CHD and other cardiac death) (Table 8). ${ }^{70,74,81,82,87}$ The trials were conducted in a total of 15,596 people with CVD including MI, arrhythmia, and CHD. Only one trial reported cardiac death to be a primary outcome (Marchioli 2002). ${ }^{70}$

## Marine Oil Versus Placebo

## CVD Population

Among people with CVD, four compared marine oil (EPA+DHA) to placebo (oleic acid or olive oil) or no intervention in a total of 12,282 participants with arrhythmia, ventricular tachycardia or fibrillation, MI, or CHD, ${ }^{70,81,82,87}$ and one compared two levels of "fish advice" (dietician to advise to increase fish and/or fish oil supplement intake) with no fish advice in a total of 3114 men with MI or angina. ${ }^{74}$

Among the four RCTs that compared marine oil (EPA+DHA) to placebo (oleic acid or olive oil) or no intervention EPA+DHA ranged from 0.8 to $2.6 \mathrm{~g} / \mathrm{d}$. In the two RCTs reporting sufficient details, the EPA to DHA ratio was 1.4. Compliance was generally good ( $>70 \%$ ). The duration of follow-up ranged from 1 to 3.5 years. Three of the four RCTs found that EPA+DHA supplementation did not have significant effects on cardiac death (OR=0.39, 0.45, and 1.01). ${ }^{82,87}$ The third RCT found that EPA+DHA supplementation had protective effects against cardiac death (RR 0.65; 95\% CI 0.51 to 0.82). ${ }^{70}$

In the study that compared "fish advice" (advise to increase fish intake in one subgroup and additional advise to take fish oil supplement in a second subgroup) with "no fish advice", ${ }^{74}$ the mean EPA intake estimated by the dietary assessment was 0.45 and $\leq 0.85 \mathrm{~g} / \mathrm{d}$ in the "fish advice" groups, and was 0.11 in the "no fish advice" group. No estimates for DHA intake levels were reported. Compliance was good (fish intake was significantly increased in the "fish advice" groups) based on the dietary assessments. The trial found that, after 9 years of followup, overall, there was a significant increase in cardiac death between 1571 men with angina who were advised to increase fish intake and 1543 men with angina who were not (adjusted HR 1.26; 95\% CI 1.00 to 1.58; $\mathrm{P}=0.047$ ). The effect was similar but nonsignificant in the subgroup of 1109 men given advice only about increasing fish intake (adjusted HR 1.20, 95\% CI 0.93 to 1.53) but larger and statistically significant in 462 men who were advised to take a fish oil supplement (adjusted HR 1.45 ; 95\% CI 1.05 to 1.99). ${ }^{74}$

## RCT Subgroup Analyses

The RCT that found a significant increased risk of cardiac death with combined fish diet and EPA+DHA supplements reported subgroup analyses for cardiac death. ${ }^{74}$ It found nonsignificant interactions between fish advice and the following five pairs of subgroups, based on whether they take nitrates, digoxin, lipid-lowering drugs, anticoagulants, or diuretics.

## Observational Studies

Two studies evaluated a composite outcome of fatal CHD and SCD, both in healthy adult males (Appendix F, Cardiac death section; Figure 10). ${ }^{54,155}$ The Health Professionals Follow-up Study found no association between EPA+DHA intake and cardiac death (Figure 10, plot \#34). The Physician's Health Study found no associations between erythrocyte ALA, EPA, DHA, DPA, SDA, or EPA+DHA+DPA levels and cardiac death. ${ }^{50,155}$

[^0]Figure 10. n-3 FA associations with cardiac death: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for cardiac death. Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted.
White squares $=$ healthy males.
Abbreviations: DHA = docosahexaenoic acid, EPA = eicosapentaenoic acid, $\mathrm{HR}=$ hazard ratio, $\mathrm{n}-3 \mathrm{FA}=$ omega-3 fatty acids.

## Coronary Heart Disease Death

## Randomized Controlled Trials

Four RCTs evaluated CHD death (Table 9). ${ }^{48,51,90,119}$ Of these, one study was conducted in 18,645 participants with dyslipidemia ( $19.5 \%$ with CHD), ${ }^{90}$ and three were conducted in a total of 6929 people with CVD including MI, arrhythmia, and CHD. Only one trial reported death to be a primary outcome (Yokoyama 2007). ${ }^{90}$

## Marine Oil Versus Placebo

## At-Risk-for-CVD Population

Among people at risk of CVD, one study compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester combined with statin with control (statin alone) in 18,645 participants with dyslipidemia ( $19.5 \%$ with CHD). ${ }^{90}$ Local physicians monitored compliance with dietary advice and medication at every clinic visit but the adherence level was not reported. This study found no significant additive effect of EPA supplementation on risk of CHD death compared with statin alone (HR 0.94; 95\% CI 0.57 to 1.56 ). When only the patients without CHD were analyzed, the study still found no significant additive effect of EPA supplementation on risk of CHD death compared with statin alone (HR 1.1; 95\% CI 0.47 to 2.6).

## CVD Population

The same study analyzed the small subgroups of patients with CVD separately. Among people with previous CHD, $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester combined with statin was compared with statin alone in 3,664 patients. No significant additive effect of EPA supplementation on risk of CHD death was found (HR 0.87; 95\% CI 0.46 to 1.64). Among 223 people with peripheral artery disease, no significant additive effect of EPA supplementation on risk of CHD death compared with statin alone was found (HR 0.48 ; 95\% CI 0.10 to 1.98). ${ }^{90}$

Among people with CVD, two studies compared marine oil (EPA+DHA) to placebo (oleic acid or olive oil) in a total of 4896 participants with arrhythmia, MI, or CHD, ${ }^{51,119}$ one was the 2-by-2 factorial RCT described under Major Adverse Cardiovascular Events. ${ }^{119}$

A relatively small trial (with 59 participants) compared $6 \mathrm{~g} / \mathrm{d}$ marine oil ( $2.88 \mathrm{~g} / \mathrm{d}$ EPA, $1.92 \mathrm{~g} / \mathrm{d}$ DHA, $1.2 \mathrm{~g} / \mathrm{d}$ DPA) to olive oil placebo for 2.4 years, with 80 percent compliance in the marine oil supplement arm (and $90 \%$ compliance in the olive oil placebo arm). ${ }^{51}$ The 2-by-2 factorial trial compared $0.4 \mathrm{~g} / \mathrm{d}$ of EPA+DHA in margarine to placebo margarine for 40 months with 90 percent compliance, overall. ${ }^{119}$ Both trials found no significant association between marine oil intake and CHD death, but the smaller trial had only one such death during its followup.

In one trial that compared "fish advice" (advise to increase fish intake) with "no fish advice" in 2033 adults, ${ }^{48}$ the mean EPA intake estimated by the dietary assessment was $0.34 \mathrm{~g} / \mathrm{d}$ in the "fish advice" group and 0.09 in the "no fish advice" group. No estimates for DHA intake levels were reported. Compliance was good based on the dietary assessments. No significant difference in risk of CHD death was found (adjusted HR $=0.92$; 95\% CI 0.66 to 1.29).

## ALA Versus Placebo

## CVD Population

The 2-by-2 factorial study compared $2 \mathrm{~g} / \mathrm{d}$ ALA in margarine to control margarine. ${ }^{119}$ The trial found no difference in risk of CHD death after 40 months (HR 0.92; 95\% CI 0.66 to 1.29).

## RCT Subgroup Analyses

Two RCTs reported subgroup analysis for CHD death (Table 10). The 2-by-2 factorial study found significant protective effect of EPA+DHA in subjects with diabetes (HR=0.51, $\mathrm{P}=0.04$ ) that was not seen in subjects without diabetes ( $\mathrm{HR}=1.21, \mathrm{P}=0.32$ ); no analysis of a statistical interaction was reported. ${ }^{119}$ In both subgroups, the effect of ALA on CHD death was nonsignificant ( $\mathrm{HR}=0.87, \mathrm{P}=0.63$ with diabetes; $\mathrm{HR}=0.97, \mathrm{P}=0.87$ without diabetes).

In the trial of participants with dyslipidemia (19.5\% of whom had CHD), ${ }^{90}$ no significant effect of EPA was found. In participants with no history of CHD (primary prevention), HR=1.00 ( $95 \%$ CI 0.32 to 3.11). In participants with a history of CHD (secondary prevention), HR=0.64 (95\% CI 0.21 to 1.94).

## Observational Studies

Ten studies evaluated associations between n-3 FA intake and biomarkers and CHD death, including the Pooling Project, which pooled data from eight large cohorts (ARIC, FMC, IWHS, NHS, VIP, WHS, ATBC, HPFS) (Appendix F, Death from coronary heart disease section; Figure 11). ${ }^{47,57,69, ~ 84, ~ 98, ~ 113, ~ 159, ~ 162, ~ 175, ~ 181, ~} 186$ The studies were all conducted in healthy adults with average followup ranging from about 6 to 24 years (median 11.3 years).

## n-3 FA Intake

Eleven studies analyzed n-3 FA intake (Alpha-Tocopherol Beta-Carotene Cancer Prevention, Cardiovascular Health Study, JACC, Japan Public Health Center-Based Study Cohort I, MORGEN, MRFIT, NIPPON DATA80, Nurses' Health Study, Pooling Project of Cohort Studies on Diet and Coronary Disease, Shanghai Women's and Men’s Health Studies, Singapore Chinese Health Study).

The NIPPON DATA80, JACC studies found no associations between total n-3 FA intake (combined) and CHD death after 13 and 24 years of followup (Figure 11, plots \#47 \& 48). ${ }^{98,175}$

The Singapore Chinese Health Study found significant associations between total n-3 FA intake and CHD death after five years of followup ( $\mathrm{P}=0.04$ ). ${ }^{170}$

Five studies, including the Pooling Project and thus comprising eight study cohorts, evaluated ALA intake (Alpha-Tocopherol Beta-Carotene Cancer Prevention, Cardiovascular Health Study, MRFIT, Pooling Project of Cohort Studies on Diet and Coronary Disease) (Figure 11, plots \#35 \& 36). ${ }^{47,57,159,170,181}$ The Singapore Chinese Health Study found significant associations between total ALA intake and CHD death after five years of followup ( $\mathrm{P}=0.001$ ). ${ }^{170}$ MRFIT found a statistically significant association between higher ALA intake measured as percent Kcal (energy) in men after about 10 years of followup (with possibly significant associations bound in quartiles with median values above about $0.5 \% \mathrm{Kcal}$ ), but no association with ALA intake measured as $\mathrm{g} / \mathrm{d} .{ }^{47}$ The other three studies also found no association (in men, women, or all healthy adults) at 6,12 , and $4-10$ years of followup.

By meta-analysis (Table 11), overall there is no statistically significant association between ALA intake and CHD death across a median dose range of 0.59 to $2.5 \mathrm{~g} / \mathrm{d}$ (effect size per $g / d=0.94 ; 95 \%$ CI 0.85 to 1.03 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.6 to $1.2 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at higher doses than at lower doses (ES above knot < ES below knot); although the differences were generally small and all were nonsignificant. The best fit curve was found with a knot at $0.9 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at $1.2 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.44)$, the highest dose threshold that could be tested.

Two studies (NIPPON DATA80, Shanghai Women's and Men's Health Studies) found no associations with EPA or DHA intake (separately) and CHD death at 24 years in one study and at about 6 years in men and 11 years in women in the other study (Figure 11, plots \#38, 39, $44 \& 45){ }^{162,175}$

Eight studies analyzed EPA+DHA (5 studies; Japan Public Health Center-Based Study Cohort I, NIPPON DATA80, Nurses' Health Study, MORGEN, Shanghai Women's and Men's Health Studies Singapore Chinese Health Study ${ }^{69,84,143,162,170,175}$ ) or EPA+DHA+DPA (2 studies; Alpha-Tocopherol Beta-Carotene Cancer Prevention, MRFIT ${ }^{47,57}$ ) between 6 and 24 years of followup. ${ }^{47}$ The studies found heterogeneous results (Figure 11, plots \#42 \& 43). Four studies (MORGEN, MRFIT, Nurses' Health Study, Singapore Chinese Health Study) found significant associations between higher EPA+DHA $\pm$ DPA and lower risk of CHD death (with significant associations occurring in quantiles with median intake of at least about $0.1 \% \mathrm{Kcal}$ or $0.25 \mathrm{~g} / \mathrm{d}) .{ }^{47,69,143,170}$ One study found an about 80 percent increase in risk of CHD death with higher EPA+DHA intake, but this was not statistically significant (Japan Public Health CenterBased Study - Cohort I, highest vs. lowest quintiles HR=1.79; 95\% CI 0.82 to 3.87; $\mathrm{P}=0.10$ across quintiles). ${ }^{84}$ The remaining three studies found no associations between EPA + DHA $\pm$ DPA and CHD death risk. Meta-analysis could not be run because intake was inconsistently measured as either $\mathrm{g} / \mathrm{d}$ or percent Kcal.

By meta-analysis (Table 12), overall there no significant association between marine oil intake and CHD death across a median dose range of 0.04 to $2.1 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=1.09$; $95 \%$ CI 0.76 to 1.57). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) found stronger associations (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1) for knots below $0.7 \mathrm{~g} / \mathrm{d}$, but stronger associations at higher doses above $0.7 \mathrm{~g} / \mathrm{d}$. However, the differences in effect size between lower and higher doses were always highly nonsignificant,
implying no difference in association. The best fit curve was found with a knot at $0.5 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at the lowest tested threshold, $0.1 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.46)$.

## n-3 FA Biomarkers

The Cardiovascular Health Study was the only study to evaluate the association between n-3 FA biomarkers and CHD death. ${ }^{159}$ At 16 years of followup, higher plasma total n-3 FA and higher plasma DHA were each significantly associated with lower risk of CHD death. No associations were found for ALA, EPA, or DPA plasma levels (Figure 11, plots \#37, 40, 41, 46, and 49).

## Observational Study Subgroup Analyses

The Pooling Project analysis of ALA, found a near-significant interaction by sex ( $\mathrm{P}=0.07$ ), suggesting that higher ALA intake may be protective against CHD death in men ( $\mathrm{HR}=0.77$; $95 \%$ CI 0.58 to 1.01) but not in women (HR=0.88; 95\% CI 0.68 to 1.14). ${ }^{181}$

## Myocardial Infarction Death

## Randomized Controlled Trials

No RCTs evaluated this outcome.

## Observational Studies

Four studies evaluated n-3 FA and MI death in healthy adults (Appendix F, Death from myocardial infarction section; Figure 12). ${ }^{68,98,113,176}$ The Shanghai study found a significant association between higher total n-3 FA intake and lower risk of MI death at 12 years of
followup, with significant associations found in quintiles with median intake above about 0.05 $\mathrm{g} / \mathrm{d}) .{ }^{162}$ In contrast, JACC found no association between total n-3 FA intake and MI death at about 13 years of followup. ${ }^{98}$ In a single analysis of EPA+DHA intake, MORGEN found a significant association between higher EPA+DHA intake and lower risk of MI death at about 11 years of followup, with a significant association found in the quartile with intake $>0.19 \mathrm{~g} / \mathrm{d} .{ }^{143}$ The VITAL study found no association between higher EPA+DHA intake in CVD adults, but did find a significant association in healthy adults $(\mathrm{P}=0.029)$. ${ }^{176}$

## Observational Study Subgroup Analyses

The Shanghai study reported no difference in association (with total n-3 FA intake) by baseline total cholesterol to HDL-c ratio. ${ }^{162}$

Figure 12. n-3 FA associations with myocardial infarction death: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for myocardial infarction death. $P$ values are the study-reported $P$ value for the trend across quantiles. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White triangles = healthy adults.
Abbreviations: DHA = docosahexaenoic acid, EPA = eicosapentaenoic acid, $\mathrm{HR}=$ hazard ratio, $\mathrm{n}-3 \mathrm{FA}=$ omega-3 fatty acids.

## Congestive Heart Failure Death

## Randomized Controlled Trials

## Marine Oil Versus Placebo

## At-Risk-for-CVD Population

One trial in 12,505 participants at risk for CVD based on multiple risk factors compared a marine oil supplement with at least $0.85 \mathrm{~g} / \mathrm{d}$ EPA+DHA with olive oil placebo (Table 13). ${ }^{160}$ The EPA to DHA ratio ranged from 0.9 to 1.5. Compliance data were not reported. After 5 years of followup, no effect on congestive heart failure (CHF) death was seen (HR=1.00; 95\% CI 0.53 to 1.88). CHF death was reported to be a secondary outcome.

## Observational Studies

Only JACC evaluated n-3 FA and CHF death (Appendix F, Death from congestive heart failure section; Figure 13). ${ }^{98}$ In healthy adults, the study found a significant association between higher total n-3 FA intake (combined) and lower risk of CHF death after about 13 years of followup, with significant associations found in quintiles with intake $>2.1 \mathrm{~g} / \mathrm{d}$.

Figure 13. n-3 FA associations with heart failure death: Observational studies

Study (or cohort) level associations between omega-3 fatty acid (n-3 FA) exposure and hazard ratio (HR) for heart failure death. $P$ values are the study-reported $P$ value for the trend across quantiles.

## Stroke Death, Total (Ischemic and Hemorrhagic)

## Randomized Controlled Trials

Three RCTs evaluated total stroke death (Table 14). ${ }^{48,96,160}$ One trial was in 12,505 participants at risk for CVD based on multiple risk factors, ${ }^{160}$ and the other two were in a total of 9008 participants with a history of MI, ${ }^{48}$ or heart failure. ${ }^{96}$ No trial reported stroke death as a primary outcome.

## Marine Oil Versus Placebo

## At-Risk-for-CVD Population

One RCT evaluated the effect of marine oil (EPA+DHA) on stroke death compared with placebo (olive oil) in a total of 12,505 participants with high risk for CVD. ${ }^{160}$ The dose of EPA+DHA was at least $0.85 \mathrm{~g} / \mathrm{d}$ (composition of the marine oil was not reported). Adherence was verified by participants’ self-report but the level of adherence was not reported. After 5 years, the study found no significant difference in stoke death comparing EPA+DHA with placebo (HR 1.05, 95\% CI 0.55 to 2.00 ). ${ }^{160}$

## CVD Population

One trial compared marine oil (EPA+DHA) ethyl ester supplementation ( $0.85-0.88 \mathrm{~g} / \mathrm{d}$ ) to placebo in 6975 participants with heart failure. ${ }^{96}$ After 3.9 years of followup, about 30 percent of participants in both study arms were not taking the supplement. No difference was found in risk of stroke death ( $\mathrm{OR}=1.13$; 95\% CI 0.75 to 1.71). A second trial compared fish advice (resulting in an average of $0.34 \mathrm{~g} / \mathrm{d}$ EPA intake) with no fish advice ( $0.09 \mathrm{~g} / \mathrm{d}$ EPA intake) in 2033 adults with a history of MI. ${ }^{48}$ Compliance was not reported. After more than 10 years of followup, no significant difference in stroke death was found (OR=1.23; 95\% CI 0.71 to 2.14).

## Observational Studies

Five studies evaluated n-3 FA intake and biomarkers and risk of total stroke death at 5, 12 to 24 years of followup in healthy adults (Appendix F, Death from stroke section; Figure 14). ${ }^{68,98,159,170,175}$

## n-3 FA Intake

Four studies evaluated n-3 FA intake and risk of stroke death (JACC, NIPPON DATA80, Shanghai, Singapore Chinese Health Study). ${ }^{68,98,170,175}$ All analyses were nonsignificant, including for total n-3 FA (combined) intake (all four studies) at 5, 12, 13, and 24 years of followup (Figure 14, plots \#61 \& 62); and EPA, DHA, and EPA+DHA intake (separately) in the NIPPON DATA80 study at 24 years of followup (Figure 14, plots \#54, 57, \& 59). ${ }^{175}$ The Singapore Chinese Health Study also found no significant associations between higher ALA or EPA + DHA intake (separately) and lower risk of stroke death. ${ }^{170}$

## n-3 FA Biomarkers

Only the Cardiovascular Health Study evaluated n-3 FA biomarkers. ${ }^{159}$ The study found near-significant associations ( $\mathrm{P}<0.10$ ) between higher plasma total n-3 FA (Figure 14, plot \#63),

DHA (Figure 14, plot \#55), and DPA levels (Figure 14, plot \#56), separately, and lower risk of stroke death after 16 years of followup ( $\mathrm{P}=0.092,0.082$, and 0.056 , respectively). The study found no association with plasma EPA levels (Figure 14, plot \#60).

## Observational Study Subgroup Analyses

The Shanghai study found no significant difference in association (of total n-3 FA intake) by baseline total cholesterol to HDL-c ratio. ${ }^{162}$

Table 14. Total stroke death: RCTs

Figure 14. n-3 FA associations with total stroke death: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted. $P$ values are the study-reported $P$ value for the trend across quantiles. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White triangles = healthy adults.
Abbreviations: ALA = alphalinolenic acid, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HR = hazard ratio, n-3 FA = omega-3 fatty acids, PPFA = plasma polyunsaturated fatty acids.

## Ischemic Stroke Death

## Randomized Controlled Trials

No RCTs evaluated this outcome.

## Observational Studies

Two studies evaluated the association between n-3 FA intake and risk of ischemic stroke death in healthy adults (Appendix F, Death from ischemic stroke section; Figure 15). ${ }^{98,162}$ Both found significant associations. JACC found an association between higher intake of total n-3 FA (combined) and lower risk of ischemic stroke death after about 13 years of followup (Figure 15, plot \#66), with significant associations found in quintiles with median intake of about $2 \mathrm{~g} / \mathrm{d}$ or more. ${ }^{98}$ The Shanghai Women's and Men's Health Studies found similar significant associations with higher EPA (particularly for median intake $>0.07 \mathrm{~g} / \mathrm{d}$ in men an $\mathrm{d}>0.06 \mathrm{~g} / \mathrm{d}$ in women), DHA (particularly for median intake $>0.15 \mathrm{~g} / \mathrm{d}$ ), and combined EPA+DHA intake (in separate analyses) with about 11 years of followup in women and 6 years of followup in men (Figure 15, plots \#64 \& 65; EPA+DHA not plotted because no data were provided for median intake per quantile). ${ }^{162}$

## Observational Study Subgroup Analyses

The Shanghai study found no significant difference in association (of total n-3 FA intake) by baseline total cholesterol to HDL-c ratio. ${ }^{162}$

Figure 15. n-3 FA associations with ischemic stroke death: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for ischemic stroke death. Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted. P values are the study-reported P value for the trend across quantiles.
White triangles = healthy adults.
Abbreviations: DHA = docosahexaenoic acid, EPA = eicosapentaenoic acid, $\mathrm{HR}=$ hazard ratio, $\mathrm{n}-3 \mathrm{FA}=$ omega-3 fatty acids.

## Hemorrhagic Stroke Death

## Randomized Controlled Trials

No RCTs evaluated this outcome.

## Observational Studies

Only the Shanghai Women's and Men's Health Studies evaluated hemorrhagic stroke death (Appendix F, Death from hemorrhagic stroke section; Figure 16). ${ }^{162}$ The study found no association between EPA, DHA, and EPA+DHA intake (not graphed because no data on median intake per quantile), separately, and risk of hemorrhagic stroke death after about 11 years followup in women and 6 years followup in men (combined analyses).

Figure 16. n-3 FA associations with hemorrhagic stroke death: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. White triangles = healthy adults.

Abbreviations: $\mathrm{DHA}=$ docosahexaenoic acid, $\mathrm{EPA}=$ eicosapentaenoic acid, $\mathrm{HR}=$ hazard ratio, $\mathrm{n}-3 \mathrm{FA}=\mathrm{omega}-3$ fatty acids.

## Death, All-Cause

## Randomized Controlled Trials

Eighteen RCTs evaluated all-cause death (Table 15). ${ }^{48,49,56, ~ 67, ~ 70, ~ 74, ~ 81, ~ 82, ~ 87, ~ 90, ~ 96, ~ 115, ~ 119, ~ 121, ~}$ ${ }^{123,146,157,160}$ Of these, one study was conducted in 12,716 generally healthy participants, ${ }^{49}$ three were in a total of 13,713 participants at risk of CVD (defined as dyslipidemia, ${ }^{90}$ hypercholesterolemia, ${ }^{115}$ or a combination of various risk factors ${ }^{160}$ ), and 14 in a total of 50,386 participants with CVD including previous persistent AFib, ${ }^{157}$ diabetes or a history of CVD, ${ }^{146}$ arrhythmia, ${ }^{82,87} \mathrm{CHD},{ }^{56}$ ventricular tachycardia or fibrillation, ${ }^{81}$ all CVD, ${ }^{123} \mathrm{MI},{ }^{48,67,70,119,121}$ heart failure, ${ }^{96}$ and angina. ${ }^{74}$ Four of the trials reported all-cause death to be a primary outcome (Burr 2003, Kromhout 2010, Marchioli 2002, Tavazzi 2008). ${ }^{70,89,96, ~} 119$

## Marine Oil Versus Placebo

Meta-analysis of the 17 RCTs of marine oil versus placebo yielded a nonsignificant summary effect size for risk of all-cause death: HR=0.97 (95\% CI 0.92 to 1.03) (Figure 17).

## At-Risk-for-CVD Population

Three RCTs compared EPA+DHA or EPA alone with placebo in participants at risk of CVD.

Among 13,068 participants, two RCTs compared marine oil (EPA+DHA) with placebo (corn or olive oil) (Figure 17). ${ }^{115,160}$ The doses of EPA+DHA were greater than 0.85 and 2.02 $\mathrm{g} / \mathrm{d}$, with EPA to DHA ratio ranging from 0.9 to 1.5 . Compliance was greater than $90 \%$ in one study and was not reported in another. The duration of followup was 3 and 5 years. Both RCTs found that EPA+DHA had no significant effect on all-cause death compared with placebo (adjusted HR $0.53,95 \%$ CI 0.27 to 1.04; HR 1.03, $95 \%$ CI 0.88 to 1.19).

One study of 18,645 patients with dyslipidemia compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester plus statin with statin alone. Compliance was monitored by local physicians but not reported in the study. Followup time was 4.6 years, and no significant additive effect of EPA supplementation on all-cause death was found (HR 1.09; 95\% CI 0.92 to 1.28 ). ${ }^{90}$

Subgroup meta-analysis (as part of a meta-analysis of all marine oil vs. placebo trials) yielded a summary HR of 1.04 ( $95 \%$ CI 0.93 to 1.16) for people at risk for CVD.

## CVD Population

Among the 14 RCTs that were conducted in participants with CVD (Figure 17), nine studies compared marine oil (EPA+DHA) with placebo, ${ }^{67,82,87,96,121,123,146,157}$ three compared marine oil (EPA+DHA) with no intervention, ${ }^{56,70,81}$ two compared "fish advice" (advise to increase fish intake in both studies with additional advise to take fish oil supplement in later study) with "no fish advice", ${ }^{48,74}$ and one was the 2-by-2 factorial RCT described under Major Adverse Cardiovascular Events that compared EPA+DHA, EPA+DHA and ALA, ALA, and oleic acid margarines. ${ }^{119}$

Among the 12 studies that compared marine oil (EPA+DHA) with placebo or no intervention, a total of 44,629 participants with CVD were examined. ${ }^{56,67,70,81,82,87,96,119,121,123,}$ ${ }^{146,157}$ The doses of EPA+DHA ranged from $0.4 \mathrm{~g} / \mathrm{d}$ to $3.32 \mathrm{~g} / \mathrm{d}$. Among the nine RCTs reporting sufficient detail, the EPA to DHA ratio ranged from 0.5 to 2. Compliance ranged from 65 to 88 percent. The duration of follow-up ranged from 1 year to more than 6 years. Two of the 12 RCTs found that EPA+DHA had significant effect on reducing all-cause death compared with placebo or no intervention in 6975 participants with heart failure (adjusted HR 0.91; 95\% CI 0.833 to 0.998 ) and in 11,332 participants with MI (RR 0.79 ; $95 \%$ CI 0.66 to 0.93 ). The other 10 RCTs found that EPA+DHA did not have significant effect on all-cause death with OR/HR ranging from 0.38 to 1.25 .

Among the two studies that compared "fish advice" with "no fish advice", ${ }^{48,74}$ a total of 5147 participant with MI or angina were examined. The mean EPA intake estimated by the dietary assessment was 0.34 and $0.45 \mathrm{~g} / \mathrm{d}$ in the "fish advice" groups, and was 0.09 and 0.11 in the "no fish advice" groups. No estimates for DHA intake levels were reported. Compliance was good (fish intake was significantly increased in the "fish advice" groups) based on the dietary assessments. Both RCTs found no significant difference in the risk of all-cause death between groups (HR 0.95 ; $95 \%$ CI 0.85 to 1.07; HR 1.15 , $95 \%$ CI 0.92 to 1.32 ).

Across the 14 RCTs of CVD populations, the summary HR (Figure 17) was 0.96 ( $95 \%$ CI 0.90 to 1.02); almost identical to the nonsignificant summary HR for all RCTs, regardless of population (HR 0.97; 95\% CI 0.92 to 1.03).

## ALA Versus Placebo

## Healthy Population

Among 12,716 healthy people, one RCT compared ALA oil (linseed oil) to control oil (sunflower seed oil). ${ }^{49}$ The doses of ALA were 5.2 and $0.13 \mathrm{~g} / \mathrm{d}$, respectively. Compliance was not reported. After 1-year followup, there was no significant difference in all-cause death between the two groups (OR 0.93; 95\% CI 0.61 to 1.44 ).

## CVD Population

Among 4837 participants with MI, the 2-by-2 factorial RCT found no significant difference in the risk of all-cause death compared with the groups received EPA+DHA alone or placebo margarines (HR 0.97; 95\% CI 0.79 to 1.19). ${ }^{119}$

## RCT Subgroup Analyses

Four RCTs included subgroup analysis for all causes of death (Table 16). All trials compared marine oil against placebo. One trial found no significant difference in effect between patients with and without hypertension ( P interaction $=0.67$ ). ${ }^{70}$ Among the two analyses of diabetes vs no diabetes subgroups neither reported a statistically significant interaction between diabetes and marine oils. ${ }^{70,96}$ One study found no interactions between marine oil and age, left ventricular ejection fraction, ischemic cause versus nonischemic cause of existing CVD, New York Heart Association level, total cholesterol, or statin use. A third study found no significant difference in effect regardless of B vitamin supplementation. ${ }^{123}$ The fourth study found no difference in effect between patients with history of CVD compared to patients without a history of CVD. ${ }^{115}$

Meta-regression of the marine oil trials found no significant interaction between n-3 FA dose ( $\mathrm{P}=0.54$ ), followup time ( $\mathrm{P}=0.19$ ), or between at risk and CVD populations $(\mathrm{P}=0.75)$

## Observational Studies

Seven studies evaluated the associations between n-3 FA intake or biomarker levels and all-cause death, mostly in healthy adults after 7 to 30 years of followup (Appendix F, All-cause death section; Figure 18); one study evaluated CVD patients with a history of MI after 4 years of followup. ${ }^{47,72,95,98,148,154,159,162,186}$ Most analyses found significant associations between higher n-3 FA intake or biomarker level and reduced risk of death.

## n-3 FA Intake

Six studies evaluated n-3 FA intake and the risk of death (Cardiovascular Health Study, JACC, MRFIT, Shanghai Women's and Men's Health Studies [two separate studies analyzed together], Takayama, VITAL). ${ }^{47,72, ~ 98, ~ 159, ~ 162, ~} 176$

JACC found no association between total n-3 FA intake (combined) and all-cause death in healthy adults after about 13 years of followup (Figure 18, plot \#79). ${ }^{98}$

Two studies evaluated ALA intake. MRFIT and the Cardiovascular Health Study both found significant associations between higher ALA intake and reduced death in healthy men after about 10 years and healthy adults $\geq 65$ years old after 12 years (Figure 18, plots \# 69 \& 70), with significant or larger associations found in median quantiles with intakes above about 1.6 $\mathrm{g} / \mathrm{d}, 1$ percent Kcal, or 2.4 percent of fat intake. ${ }^{47,159}$

In a combined analysis (of women and men), the Shanghai Women's and Men's Health Studies found a significant associations between higher EPA and DHA intakes (separately) and reduced death after about 11 years of followup in the women and 6 years of followup in the men (Figure 18, plots \#72 \& 77), with significant associations found for quintiles with median intakes above $0.01 \mathrm{~g} / \mathrm{d}$ of EPA and above $0.02 \mathrm{~g} / \mathrm{d}$ of DHA. ${ }^{162}$

Four studies found heterogeneous associations between EPA+DHA (or EPA + DHA + DPA) intake and death risk (Figure 18, plots \#75 \& 76). MRFIT found nearsignificant associations between higher marine oil intake and death after 10 years of followup $(\mathrm{P}<0.10) .{ }^{47}$ The Takayama study found no association in healthy men, but significantly lower
death among women with higher marine oil intake after 7 years of followup. ${ }^{72}$ The combined Shanghai Women's and Men's Health Studies found a significant association between higher marine oil intake and lower risk of death in women after 11 years of followup and men after 6 years of followup. ${ }^{162}$ The VITAL study found a significant association between higher marine intake and lower risk of death in healthy adults after 6 years of followup ( $\mathrm{P}=0.004$ ). ${ }^{176}$ Across studies, associations were large or near-significant ( $\mathrm{P}<0.10$ ) in quantiles with median intake above about 0.3 percent Kcal or about 0.7 or $1.2 \mathrm{~g} / \mathrm{d}$.

By meta-analysis (Table 17), overall there no significant association between marine oil intake and all-cause death across a median dose range of 0.066 to $1.58 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=$ 0.62 ; $95 \%$ CI 0.31 to 1.25 ). However, meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) consistently found stronger associations (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1). This implies the possibility of a ceiling effect (where intake above a certain level adds no further benefit). For thresholds $\leq 0.4 \mathrm{~g} / \mathrm{d}$ the associations are statistically significant at lower doses, but not statistically significant at higher doses. The difference between low- and high-dose associations is statistically significantly different at a threshold of $0.2 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.047)$. The best fit curve was found with a knot at $0.3 \mathrm{~g} / \mathrm{d}$. This analysis may suggest that marine oil intake above about 0.2 to $0.4 \mathrm{~g} / \mathrm{d}$ may not further strengthen any association between higher marine oil intake and lower rate of all-cause death.

The VITAL study found a significant association between higher EPA and DHA intake (separately) and lower risk of death in healthy adults after 6 years of followup (EPA: $\mathrm{P}=0.014$, DHA: $\mathrm{P}=0.004) .{ }^{176}$

## n-3 FA Biomarkers

Three studies evaluated associations between n-3 FA biomarkers and risk of death, two in healthy adults, one in CVD patients with a history of MI.

The Cardiovascular Health Study found a significant association between higher plasma n-3 FA levels (combined) and risk of death in healthy adults $\geq 65$ years after 16 years of followup (Figure 18, plot \#80). ${ }^{148}$

Two studies evaluated ALA biomarkers (Figure 18, plot \#71). The Cardiovascular Health Study and ULSAM found no significant associations between plasma ALA and risk of death at 16 and 31 years of followup in healthy adults. ${ }^{95,148}$

Three studies evaluated EPA biomarkers (Figure 18, plot \#78), one in a CVD population. The Osaka Acute Coronary Insufficiency Study found no association between blood EPA levels and death in patients with a history of MI after 4 years of followup. Similarly, ULSAM found no association with plasma EPA after 31 years of followup. ${ }^{95}$ In contrast, the Cardiovascular Health Study found a significantly lower risk of death with higher plasma EPA levels after 16 years of followup in healthy adults $\geq 65$ years old. ${ }^{148}$

The same three studies evaluated DHA biomarkers (Figure 18, plot \#73). In contrast with its finding regarding blood EPA levels, the Osaka Acute Coronary Insufficiency Study found a significant association between higher blood DHA levels and reduced death. In ULSAM and the Cardiovascular Health Study, findings were concordant between blood EPA and DHA levels, such that the former found no association with death and the latter found a significant association between higher plasma DHA levels and lower death. ${ }^{95,148}$

The Cardiovascular Health Study also found a significant association between higher plasma DPA levels and lower all-cause death in healthy adults (Figure 18, plot \#74).

## Observational Study Subgroup Analyses

Three observational studies conducted subgroup analyses of the associations between n-3 FA and all-cause death (Table 18). The Takayama study implied no difference in association of EPA + DHA intake between men and women. ${ }^{72}$ The Cardiovascular Health Study found no difference in association of intake of or plasma ALA based on baseline fish consumption. ${ }^{148}$ The Osaka Acute Coronary Insufficiency Study evaluated 12 sets of subgroups for both blood DHA and blood EPA, as listed in Table 18. A statistically significant interaction was found between blood EPA and hypertension (P interaction = 0.015). In participants with hypertension, no association was found between blood EPA and risk of death (HR=0.96); however, in participants with no hypertension, higher blood EPA was associated with higher risk of dying (HR=8.23). The study also found near-significant interactions between blood EPA and diabetes (P interaction $=0.089$, favoring those without diabetes) and statin use (P interaction $=0.062$, favoring those not using statins).

## Coronary Heart Disease, Incident

## Randomized Controlled Trials

No RCT evaluated incident CHD.

## Observational Studies

Eleven studies evaluated the associations between intake and biomarkers of n-3 FA and incident CHD (Appendix F, Coronary heart disease section; Figure 19). ${ }^{54,57,69,78,84,127,135,148,149,}$ 171, 172, 186 . Definitions of CHD outcomes varied across studies, but mostly included both fatal and nonfatal events. All studies were conducted in generally healthy adults. The median followup duration across studies was 11.5 years (range of average followup 6 to 23 years). Studies found a
mix of both significant associations between higher n-3 FA intake or biomarker levels and lower risk of CHD or a lack of associations.

## n-3 FA Intake

Ten studies evaluated n-3 FA intake and risk of CHD (Alpha-Tocopherol, Beta-Carotene Cancer Prevention, Cardiovascular Health Study, Glostrup Population Studies, Health Professional Follow-up Study, Japan Public Health Center-Based Study - Cohort I, MESA, MORGEN, Nurses' Health Study, Pooling Project of Cohort Studies on Diet and Coronary Disease, Spanish EPIC).

Six studies evaluated ALA intake with 6 to 23 years of followup (Pooling Project of Cohort Studies on Diet and Coronary Disease, Alpha-Tocopherol Beta-Carotene Cancer Prevention, Cardiovascular Health Study, Glostrup Population Studies, MESA, MORGEN). One of these studies, the Pooling Project, pooled data from eight large cohorts (ARIC, FMC, IWHS, NHS, VIP, WHS, ATBC, HPFS); thus, overall 13 study cohorts were included (Figure 19, plot \#81). Individually, none of the studies found associations between ALA intake and CHD.

By meta-analysis (Table 19), overall there is no association between ALA intake and CHD across a median dosage range of 0.2 to $2.5 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.97$; $95 \%$ CI 0.92 to 1.03). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.4 \mathrm{~g} / \mathrm{d}$ ) consistently found marginally smaller ES at lower doses than at higher doses. At no dose threshold was there a statistically significant difference between the ES below the dose threshold (knot) and above the threshold. The best fit curve was found with a knot at $0.7 \mathrm{~g} / \mathrm{d}$, the threshold that also had the lowest P value ( $\mathrm{P}=0.34$ ).

For both EPA and DHA, separately, two studies evaluated associations with CHD, both at about 10 years of followup (Figure 19, plots \#84 \& 93). Spanish EPIC found no associations between DHA or EPA intake and CHD in either men or women (analyzed separately). ${ }^{172}$ MESA found near-significant associations ( $\mathrm{P}=0.09$ DHA and 0.06 EPA) between higher DHA and EPA intake and lower risk of CHD. ${ }^{171}$

Only MESA evaluated DPA intake, finding significantly lower risk of CHD among those with higher DPA intake after 10 years of followup (Figure 19, plot \#87). ${ }^{171}$

Seven studies evaluated intake of EPA+DHA (five studies) or EPA+DHA+DPA (two studies) with 6 to 23 years of followup (Alpha-Tocopherol Beta-Carotene Cancer Prevention, Glostrup Population Studies, Health Professional Follow-up Study, Japan Public Health CenterBased Study - Cohort I, MESA, Nurses’ Health Study, Spanish EPIC) (Figure 19, plots \#90 \& 91). Individually, studies found variable associations. In two analyses of combined men and women (Japan Public Health Center-Based Study - Cohort I, MESA), neither found a significant association at 10 and 11.5 years of followup (although, MESA found a lower risk with higher EPA + DHA + DPA intake at $\mathrm{P}=0.08$ ). ${ }^{84,171}$ Three studies analyzed associations in women specifically (Glostrup Population Studies, Nurses’ Health Study, Spanish EPIC). The Nurses’ Health Study and Glostrup Population Studies found significantly lower risk of CHD with higher EPA+DHA intake; ${ }^{69,135}$ the Spanish EPIC study also found lower HRs with higher intake but the association was nonsignificant. ${ }^{172}$ Four studies analyzed men specifically (Alpha-Tocopherol Beta-Carotene Cancer Prevention, Glostrup Population Studies, Health Professional Follow-up Study, Spanish EPIC). All found no significant associations; however, in contrast with the studies of all adults or of women, the direction of the associations suggested higher risk of CHD among men with higher marine oil intake at baseline. ${ }^{54,57,135,172}$

By meta-analysis (Table 20), overall there no significant association between marine oil intake and CHD across a median dose range of 0.038 to $3.47 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.94$; $95 \%$ CI 0.81 to 1.10 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.4 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1, ES above know about 1). At all knot points the differences were nonsignificant. This weakly suggests the possibility of a floor effect (where intake above a certain minimum amount is needed before any benefit accrues). The best fit curve was found with a knot at $0.4 \mathrm{~g} / \mathrm{d}$. The P values for differences between lower- and higher-dose knots were between 0.12 and 0.14 at all knots $\geq 0.3 \mathrm{~g} / \mathrm{d}$.

| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 178,005 | $0.038-3.47$ | NA | $0.94(0.81,1.10)$ |  |  |  |  |  |

* ES below vs. above knot

Abbreviations: AIC = Akaike information criterion (estimation of fit of regression with spline), CHD = coronary heart disease, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA $=$ eicosapentaenoic acid, $\mathrm{ES}=$ effect size, NA $=$ not applicable.

## n-3 FA Biomarkers

Three studies analyzed n-3 FA biomarkers (Cardiovascular Health Study, EPIC Norfolk, MESA) in healthy adults (men and women combined) with 10,13 , and 16 years of followup. ${ }^{149,}$ 159, 171

The two studies that evaluated blood or plasma levels of total n-3 FA combined had conflicting findings regarding the association between total n-3 FA biomarkers and risk of CHD (Figure 19, plots \#96 \& 97). EPIC Norfolk found no evidence of an association between blood levels of total n-3 FA and risk of CHD at 13 years, ${ }^{149}$ but the Cardiovascular Health Study found a significantly lower risk of CHD at 16 years with higher total n-3 FA plasma levels. ${ }^{148,159}$

All three studies (Cardiovascular Health Study, EPIC Norfolk, MESA) found no association between ALA blood, plasma, or phospholipid levels and risk of CHD (Figure 19, plots \#82 \& 83). ${ }^{149,159,171}$

All three studies evaluated both EPA and DHA blood, plasma, or phospholipid levels (separately for each n-3 FA) and found similar associations for the two n-3 FA (Figure 19, plots \#85, 86, 94, \& 95). The Cardiovascular Health Study and MESA both found lower risk of CHD associated with higher baseline EPA and DHA levels. ${ }^{148,159,171}$ EPIC Norfolk found no association. ${ }^{149}$

The three studies also evaluated DPA blood, plasma, or phospholipid levels, but each study had the opposite findings as for EPA and DHA biomarkers (Figure 19, plots \#88 \& 89). The Cardiovascular Health Study and MESA found no significant association with CHD (although the HR estimates also favored lower CHD with higher DPA levels). ${ }^{148,159,171}$ EPIC Norfolk found a significantly lower risk of CHD with higher DPA blood levels. ${ }^{149}$

The MESA study found a significant association between combined EPA+DHA+DPA phospholipid levels and lower risk of CHD (Figure 19, plot \#92). ${ }^{171}$

## Observational Study Subgroup Analyses

The Pooling Project found a stronger, almost significant, association between ALA intake and incident CHD in men ( $\mathrm{HR}=0.85$; $95 \%$ CI 0.72 to 1.01 ) than in women ( $\mathrm{HR}=1.02$; 95\% CI 0.65 to 1.59), but did not report whether these associations were significantly different from each other (whether there was an interaction). ${ }^{181}$ The Cardiovascular Health Study found no difference in associations between ALA (plasma or intake) and incident CHD between men and women or between those with higher versus lower (or no) fish intake at baseline. ${ }^{148}$

Figure 19. n-3 FA associations with incident coronary heart disease: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted. $P$ values are the study-reported $P$ value for the trend across quantiles. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White triangles = healthy adults, black circles = adults with dyslipidemia (at risk), white squares = healthy males, black squares $=$ healthy females.

Abbreviations: ALA = alphalinolenic acid, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, FA = fatty acid, HR = hazard ratio, n-3 FA = omega-3 fatty acids, PPFA = plasma polyunsaturated fatty acids.

## Myocardial Infarction, Total (Fatal and Nonfatal)

## Randomized Controlled Trials

Eleven RCTs evaluated risk of MI (Table 21). ${ }^{48,49,51,81,87,90,96,123,146,157,160}$ Of these, one study was conducted in 12,716 generally healthy participants, ${ }^{49}$ three were in a total of 27,938 participants at risk of CVD (defined as previous stable angina, ${ }^{49}$ dyslipidemia, ${ }^{90}$ or a combination of various risk factors, ${ }^{160}$ and nine were in a total of 29,338 participants with CVD including $\mathrm{MI},{ }^{48,49,160} \mathrm{CHD},{ }^{51,90}$ diabetes, and history of CVD, ${ }^{146}$ all CVD, ${ }^{123}$ heart failure, ${ }^{96}$ previous persistent AFib, ${ }^{157}$ ventricular tachycardia or fibrillation, ${ }^{81}$ and arrhythmia. ${ }^{87}$ One of the marine oil trials reported separate analyses for at risk and CVD populations. ${ }^{90}$ One of the ALA trials reported separate analyses for all three population groups. ${ }^{49}$ Three of the trials reported incident MI to be a primary outcome (Bosch 2012, Burr 1989, Galan 2010); however Galan recorded MI as a secondary outcome in the ISRCTN registry). ${ }^{48,123,146}$

## Marine Oil Versus Placebo

Meta-analysis of the 11 RCTs of marine oil versus placebo yielded a significant summary effect size for lower risk of MI: HR=0.88 ( $95 \%$ CI 0.77 to 1.02) (Figure 20).

## At-Risk-for-CVD Population

Two RCTs comparing marine oils to control were conducted in participants at increased risk of CVD. ${ }^{90,160}$ One compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA combined with statin with control (statin alone) in 14,981 participants with dyslipidemia (without CHD), ${ }^{90}$ and one compared marine oil (EPA+DHA) with placebo (olive oil) in 12,505 participants with a combination of various risk factors. ${ }^{160}$ Compliance was not reported in either study. After 5-year followup, the EPA (and statin) study showed no significant additive effect of EPA on statin use to reduce the risk of MI compared with statin alone (HR 0.79; 95\% CI 0.52 to 1.19). In the RCT of EPA+DHA, ${ }^{160}$ the dose of EPA+DHA was less than $0.85 \mathrm{~g} / \mathrm{d}$ with a EPA to DHA ratio between 0.9 and 1.5. After 5-year followup, this study found that EPA+DHA had no significant effect on risk of MI compared with placebo (HR 0.76; 95\% CI 0.34 to 1.74)

Subgroup meta-analysis (as part of a meta-analysis of all marine oil vs. placebo trials) yielded a nonsignificant summary HR of 0.77 ( $95 \%$ CI 0.57 to 1.03 ) for people at increased risk for CVD.

## CVD Population

Nine RCTs of participants with a history of CVD evaluated EPA+DHA supplementation or fish advice to placebo (or no fish advice) in a total of 28,314 participants. ${ }^{48,51,81,87,90,96,123,146,}$
${ }^{157}$ Followup duration ranged from 1 to over 6 years. Among the nine EPA+DHA trials, total
dose of marine oil ranged from 0.6 to $6 \mathrm{~g} / \mathrm{d}$; the fish advice trial compared $0.34 \mathrm{~g} / \mathrm{d}$ (based on food frequency questionnaire) to $0.09 \mathrm{~g} / \mathrm{d}$. Among five of the RCTs, the ratio of EPA to DHA ranged from 0.83 to 2 . None of the trials found a statistically significant effect of marine oil on risk of MI, with effect sizes ranging from 0.33 ( $95 \%$ CI 0.03 to 3.19 ) to 1.10 ( $95 \%$ CI 0.07 to 17.9). The RCT that compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester plus statin with statin alone also analyzed the 3,884 patients with either CHD or peripheral artery disease separately. Followup time was 5 years and compliance was not reported. There was no significant additive effect of EPA supplementation on risk of MI (HR 0.75 ; $95 \%$ CI 0.47 to 1.19 and OR 0.67 ; $95 \%$ CI 0.15 to 3.07). ${ }^{90}$

Across the nine RCTs of CVD populations, the summary HR (Figure 20) was 0.91 ( 0.78 to 1.06); almost identical to the near-significant summary HR for all RCTs, regardless of population (HR 0.88; 95\% CI 0.77 to 1.02).

## ALA Versus Placebo

## Healthy Population

A single trial from 1965 compared linseed oil (ALA $5.2 \mathrm{~g} / \mathrm{d}$ ) to sunflower seed oil (ALA $0.13 \mathrm{~g} / \mathrm{d}$ ) in 12,716 healthy adults. After 1 year of followup, no effect of ALA was found on risk of MI (OR=0.99; 95\% CI 0.67 to 1.45). ${ }^{49}$

## At-Risk-for-CVD Population

The same trial from 1965 compared linseed oil (ALA $5.2 \mathrm{~g} / \mathrm{d}$ ) to sunflower seed oil (ALA $0.13 \mathrm{~g} / \mathrm{d}$ ) in 452 adults with previous angina pectoris but no infarction. After 1 year of followup, those on ALA supplementation had a significantly lower risk of MI (OR=0.17; 95\% CI 0.04 to $0.79) .{ }^{49}$

## CVD Population

One ALA trial from the 1960s reported analyses of the effect of ALA in participants with a history of MI in a total of 438 people. The trial used linseed oil as the source of ALA ( $5.2 \mathrm{~g} / \mathrm{d}$ ) compared with sunflower seed oil ( $0.13 \mathrm{~g} / \mathrm{d}$ ALA). It found no significant effect of ALA on risk of a subsequent MI (OR 0.84). ${ }^{49}$

## RCT Subgroup Analyses

One trial of EPA+DHA $0.6 \mathrm{~g} / \mathrm{d}$ versus placebo, in 2501 people with a history of any CVD found no difference in effect on risk of MI of marine oil in participants also taking B vitamins or not. ${ }^{123}$

Meta-regression of the marine oil trials found no significant interaction between n-3 FA dose ( $\mathrm{P}=0.09$ ) or between at risk and CVD populations ( $\mathrm{P}=0.40$ ), but a significant interaction was found for followup time ( $\mathrm{P}<0.01$ ).

## Observational Studies

Three studies evaluated the associations between n-3 FA intake or biomarker level and MI risk in healthy adults, mostly men, in 4 to 11.5 years (Appendix F, Myocardial Infarction section; Figure 21). ${ }^{50,52,54,84,191}$ Most analyses found no association. The Physicians Health Study found no association between intake of total n-3 FA (combined) and risk of MI in healthy men at 4 years of followup (Figure 21, plot \#99). The two studies that evaluated marine oil
(EPA+DHA) intake had different findings (Figure 21, plot \#98). The Health Professional Follow-up Study found no significant association among healthy men at 6 years of followup. ${ }^{54}$ The Japan Public Health Center-Based Study - Cohort I study found lower risk of MI among healthy adults (men and women combined) with higher EPA+DHA intake. ${ }^{84}$

Only the Physicians Health Study evaluated associations of n-3 FA biomarkers and MI. The study found no associations with cholesteryl ester or phospholipid levels of EPA, DHA, or combined EPA+DHA.

Figure 21. n-3 FA associations with myocardial infarction: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for myocardial infarction. Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted. $P$ values are the study-reported $P$ value for the trend across quantiles. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White triangles = healthy adults, black squares = healthy males.
Abbreviations: DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HR = hazard ratio, n-3 FA = omega-3 fatty acids.

## Revascularization

## Randomized Controlled Trials

Six RCTs evaluated coronary revascularization as an outcome (Table 22). ${ }^{67,81, ~ 90,121,123,}$
${ }^{146}$ Of these, one was conducted in 18,645 hypercholesterolemic participants ( $19.5 \%$ with CHD), ${ }^{90}$ and five were in a total of 20,669 participants with CVD including diabetes and history of CVD,,${ }^{146}$ all CVD, ${ }^{123}$ patients with implantable defibrillators, ${ }^{81}$ and MI. ${ }^{67,121}$ None of the trials reported revascularization to be a primary outcome.

## Marine Oil Versus Placebo

## At-Risk-for-CVD Population

Among 18,645 hypercholesterolemic participants (19.5\% with CHD), one RCT compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester combined with statin with control (statin alone) for a duration of 5 years. ${ }^{90}$ Adherence was not reported. There was no significant difference in the risk of coronary artery bypass between the two groups ( $\mathrm{HR}=0.86$; $95 \% \mathrm{CI} 0.71$ to 1.05 ). A subgroup analysis among 14,981 hypercholesterolemic participants without previous CHD showed similar finding ( $\mathrm{HR}=0.87$; 95\% CI 0.62 to 1.21).

## CVD Population

Among participants with CVD, five studies compared marine oil (EPA + DHA) to placebo (olive oil or corn oil) in a total of 19,241 participants. ${ }^{67,81,121,123,146}$. The dose of EPA+DHA ranged from 0.6 to $1.7 \mathrm{~g} / \mathrm{d}$, and the EPA to DHA ratio ranged from 0.5 to 2 . Reported in three studies, compliance was more than 70 percent. The mean duration of followup ranged from 1 to more than 6 years. All five studies found that EPA+DHA supplementation had no significant effect on revascularization compared with placebo with HR/OR ranging from 0.49 to 0.97.

One other study compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester combined with statin with control (statin alone) in a subgroup of 3664 patients with previous CVD (HR=0.87; 95\% CI 0.69 to 1.1) and 283 peripheral artery disease patients (HR=0.40; 95\% CI 0.14 to 1.05 ) also did not find significant effect on the risk of coronary artery bypass. ${ }^{90}$

## Observational Studies

Only the Health Professional Follow-up Study analyzed coronary revascularization (Appendix F, Coronary artery bypass graft surgery section; Figure 22). ${ }^{54}$ The study found no significant association in healthy men between intake of combined EPA + DHA and risk of undergoing coronary artery bypass grafting after 6 years of followup ( $\mathrm{P}=0.09$ ).

Figure 22. n-3 FA associations with coronary revascularization: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted. $P$ values are the study-reported $P$ value for the trend across quantiles.
White squares = healthy males
Abbreviations: DHA = docosahexaenoic acid, EPA = eicosapentaenoic acid, $\mathrm{HR}=$ hazard ratio, $\mathrm{n}-3 \mathrm{FA}=$ omega -3 fatty acids.

## Acute Coronary Syndrome

## Randomized Controlled Trials

No RCT evaluated acute coronary syndrome.

## Observational Studies

One study (Diet, Cancer, Health) evaluated the associations between multiple n-3 FA measures and acute coronary syndrome (MI or unstable angina) after a mean of 7.6 years in a healthy population (age 50-64 y) (Appendix F, Acute coronary syndrome section; Figure 23). ${ }^{134}$ Analyses were conducted separately for men and women; for DHA, DPA, EPA, and EPA + DHA + DPA; and for each n-3 FA type, both intake and adipose tissue percent FA. For both men and women, the intake levels of total n-3 FA were not associated with future acute coronary ischemia (Figure 23, plots \#102, 104, 106, \& 108). Among men, higher baseline adipose tissue DHA, DPA, and EPA+DHA+DPA, but not EPA, were significantly associated with decreased risk of acute coronary ischemia, based on both a 0.1 percent increase in baseline measure and comparing the highest and lowest quantiles for each n-3 FA adipose tissue level (Figure 23, plots \#101 103, 105, \& 107). Among women, no statistically significant associations between baseline biomarker level and outcome were found.

Figure 23. n-3 FA associations with acute coronary syndrome: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. $P$ values are the study-reported $P$ value for the trend across quantiles. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White squares $=$ healthy males, black squares $=$ healthy females.
Abbreviations: DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HR = hazard ratio, n-3 FA = omega-3 fatty acids.

## Angina Pectoris

## Randomized Controlled Trials

Seven trials evaluated angina pectoris (Table 23). Three RCTs evaluated stable angina, ${ }^{49}$, ${ }^{86,87,146}$, one evaluated hospitalization for angina, ${ }^{81}$ and three evaluated unstable angina. ${ }^{51,67,90}$ Only one trial reported unstable angina to be a primary outcome (Sacks 1995). ${ }^{51}$ Meta-analysis was not conducted due to the heterogeneity of specific outcomes analyzed by the primary studies.

## Marine Oil Versus Placebo

## At-Risk-for-CVD Population

One study compared $1.8 \mathrm{~g} / \mathrm{d}$ purified EPA combined with statin with control (statin alone) to placebo with statin in 18,645 participants with dyslipidemia ( $19.5 \%$ with CHD) ${ }^{90}$ Adherence was verified by local physicians at every clinic visit but the level was not reported. After 5 years of followup, the trial found a significant risk reduction in unstable angina pectoris events (HR $0.7695 \%$ CI 0.62 to 0.95 ) in participants who were assigned to the EPA+statin group compared to those in the statin alone group.

## CVD Population

Five trials were conducted in a total of 13,641 patients with documented CVD, CHD or MI. ${ }^{51,67,81,86,146}$ The dose of EPA+DHA ranged from 0.84 to $6 \mathrm{~g} / \mathrm{d}$, and the EPA to DHA ratio ranged from 1.24 to 2 . Reported in two studies, compliance was more than 80 percent, and one study used n-3 FA biomarkers to monitor the adherence. The mean duration of followup ranged from 1 to more than 6 years. All five studies found that EPA+DHA supplementation had no significant effect on the risk for angina compared with placebo with HR/OR ranging from 0.64 to 1.18 .

One other study compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester combined with statin with control (statin alone) found that EPA had significant additive effect on reducing the risk of unstable angina in a subgroup of 3664 patients with previous CVD (HR=0.72; 95\% CI 0.55 to 0.95 ), but the effect was not significant in a subgroup of 283 peripheral artery disease patients (HR=0.56; $95 \%$ CI 0.17 to 1.71). ${ }^{90}$

## ALA Versus Placebo

## Healthy Population

One trial compared linseed oil ( $5.2 \mathrm{~g} / \mathrm{d}$ ALA) to a control oil (sunflower seed oil, $0.13 \mathrm{~g} / \mathrm{d}$ ALA) for a duration of 1 year among 13,628 generally healthy participants. ${ }^{49}$ Adherence was
verified at follow-up by participating physicians but level was not reported. This study found no significant effect on stable angina between the two groups (OR 1.58 95\% CI 0.77 to 3.26).

## Observational Studies

No observational studies evaluated angina pectoris, per se.

# Stroke, Total (Ischemic and Hemorrhagic, Fatal and Nonfatal) 

## Randomized Controlled Trials

Eight RCTs evaluated total stroke (Table 24). ${ }^{49,51,70, ~ 90, ~ 96, ~ 123, ~ 146, ~} 157$ One was conducted in 13,406 healthy participants, ${ }^{49} 18,645$ participants with dyslipidemia ( $19.5 \%$ with CHD) ${ }^{90}$, and the other six included a total of 33,981 participants with CVD and/or diabetes, ${ }^{123,146} \mathrm{MI}^{51}{ }^{51,70}$ persistent AFib, ${ }^{157}$ and heart failure. ${ }^{96}$ None of the trials reported total stroke to be a primary outcome.

## Marine Oil Versus Placebo

Meta-analysis of the seven RCTs of marine oil versus placebo yielded a nonsignificant summary effect size for risk of MI: HR=0.98 (95\% CI 0.88 to 1.09) (Figure 24). ${ }^{51,70,90,96, ~ 123, ~ 146, ~}$ 157

## At-Risk-for-CVD Population

One study compared $1.8 \mathrm{~g} / \mathrm{d}$ purified EPA combined with statin with control (statin alone) to placebo with statin in 18,645 participants with dyslipidemia ( $19.5 \%$ with CHD) ${ }^{90}$ Adherence was verified by local physicians at every clinic visit but the level was not reported. After 5 years of followup, the trial did not find significant difference in the risk of total stroke between participants who were assigned to the EPA+statin group and those in the statin alone group (HR=1.02; 95\% CI 0.91 to 1.13).

## CVD Population

Seven RCTs of participants with a history of CVD evaluated EPA $\pm$ DHA supplementation. ${ }^{51,70,90,96,123,146,157}$ Followup duration ranged from 1 to at least 6 years. The total dose of marine oil ranged from 0.6 to $6 \mathrm{~g} / \mathrm{d}$. Among four of the studies the EPA to DHA ratio ranged from 0.8 to 2 . The six studies of EPA+DHA found a statistically significant effect of marine oil on risk of stroke, mostly with wide confidence intervals, and with effect sizes ranging from 0.92 ( $95 \%$ CI 0.79 to 1.08 ) to 2.8 ( $95 \%$ CI 0.11 to 71.6 ). The one study that compared 1.8 g/d EPA ethyl ester combined with statin with control (statin alone) found that EPA had significant additive effect on reducing the risk of total stroke in a subgroup of 942 patients with previous CHD (HR=0.80; 95\% CI 0.64 to 0.997). ${ }^{90}$

Across the seven RCTs of CVD populations, the summary HR (Figure 24) was 0.97 (95\% CI 0.83 to 1.13).

## ALA Versus Placebo

## Healthy Population

One RCT of 13,406 healthy participants compared linseed oil ( $5.2 \mathrm{~g} / \mathrm{d}$ ALA) to a control oil (sunflower seed oil with $0.13 \mathrm{~g} / \mathrm{d}$ ALA). ${ }^{49}$ Adherence was not reported. After 1 year of follow up, the trial found no significant effect of ALA on stroke (OR=1.33; 95\% CI 0.56 to 3.16).

## RCT Subgroup Analyses

Meta-regression of the marine oil trials found no significant interaction between n-3 FA dose ( $\mathrm{P}=0.06$ ), followup time ( $\mathrm{P}=0.08$ ), or between at risk and CVD populations $(\mathrm{P}=0.08)$

## Observational Studies

Six studies evaluated the associations between n-3 FA intake or biomarker level and risk of total stroke in healthy adults in 4 to 16 years (Appendix F, Stroke section; Figure 25). ${ }^{50,}$ 65, 73, 138, 143, 145, 159, 186 Most analyses found no association between n-3 FA intake and total stroke risk and all found no significant association with n-3 FA biomarker level.

## n-3 FA Intake

All six studies evaluated n-3 FA intake (Cardiovascular Health Study, Health Professional Follow-up Study, MORGEN, Nurses' Health Study, Physician's Health Study, Swedish Mammography Study). Among analyses the only significant associations were found in women.

In a study of healthy men, the Physicians Health Study found no significant association between intake of total n-3 FA (combined) and total stroke after 4 years of followup (Figure 25, plot \#115)

Three studies evaluated ALA intake (Figure 25, plot \#109). Two studies (Cardiovascular Health Study, Swedish Mammography Study) found no significant association after 10 and 12 years. The third study, MORGEN, did not report a $P$ value for trend across quintiles, but found lower risk for stroke in all quintiles (at 10 years) compared with the lowest, the middle three of which were statistically significant (with median intake above about $1.25 \mathrm{~g} / \mathrm{d}$ ).

Four studies evaluated combined EPA+DHA intake (Figure 25, plot \#113). Three analyses were conducted in women and two in men. In analyses of women, MORGEN and the Swedish Mammography Study found significant associations between higher EPA+DHA (particularly with median intake of at least $0.56 \mathrm{~g} / \mathrm{d}$ or $>0.19 \mathrm{~g} / \mathrm{d}$ ) and lower risk of stroke at 10 years of followup, but the Nurses’ Health Study found no significant association. Both the Health Professional Follow-up Study and the MORGEN analysis of men found no significant association.

## n-3 FA Biomarkers

Two studies (Cardiovascular Health Study, MORGEN) evaluated plasma n-3 FA levels in healthy adults at 10 and 16 years. All analyses were not statistically significant. The Cardiovascular Health Study found no association with total n-3 FA plasma levels (combined, Figure 25, plot \#116). Both studies found no association with plasma ALA (Figure 25, plot \#110). In contrast with all other analyses, MORGEN found a near-significant increased risk ( $\mathrm{P}<0.10$ ) of total stroke among adults with higher EPA + DHA levels measured as a continuous variable ( $\mathrm{OR}=1.16$ per percentage unit FA; 95\% CI 0.94 to 1.45 ; $\mathrm{P}=0.07$ ). The Cardiovascular Health Study found no associations for EPA, DHA, and DPA plasma levels (separately, Figure 25, plots \#111, 112, \& 114).

By meta-analysis (Table 25), overall there is a statistically significant association between marine oil intake and total stroke across a median dosage range of 0.025 to $0.6 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.68 ; 95 \%$ CI 0.53 to 0.87 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found a much stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below know less than 1; ES above know greater than 1); although, the difference in effect sizes above and below the knots were never statistically significant This implies a possible ceiling effect ceiling effect (where intake above a certain level adds no further benefit).
However, given that the differences between lower and higher dose ES remained large across the
range of testable dose thresholds, the actual ceiling dose threshold may be above the analyzable range (i.e., $>0.5 \mathrm{~g} / \mathrm{d}$ ). The best fit curve was found with the lowest knot at $0.1 \mathrm{~g} / \mathrm{d}$. The P values for differences between lower- and higher-dose effect sizes ranged from 0.14 to 0.20 .

## Observational Study Subgroup Analyses

The Cardiovascular Health Study found no difference in associations of ALA intake or plasma values and total stroke by amount of fish consumption at baseline or by sex. The Health Professional Follow-up Study found no difference in association between EPA+DHA intake and ischemic stroke based on whether participants used fish oil supplements.

## Stroke, Ischemic (Fatal and Nonfatal)

## Randomized Controlled Trials

Two RCTs evaluated ischemic stroke (Table 26). ${ }^{90,96}$ One was conducted in 18,645 participants with dyslipidemia (19.5\% with CHD) and performed a subgroup analysis in 942 patients with previous CHD, ${ }^{90}$ and the other was conducted in 6975 participants with heart failure. ${ }^{96}$ Both trials evaluated n-3 FA ethyl esters. Neither of the trials reported ischemic stroke to be a primary outcome.

## At-Risk-for-CVD Population

One study compared $1.8 \mathrm{~g} / \mathrm{d}$ purified EPA combined with statin with control (statin alone) to placebo with statin in 18,645 participants with dyslipidemia ( $19.5 \%$ with CHD) ${ }^{90}$ Adherence was verified by local physicians at every clinic visit but the level was not reported. After 5 years of followup, the trial did not find significant difference in the risk of ischemic stroke between participants who were assigned to the EPA+statin group and those in the statin alone group (HR=0.97; 95\% CI 0.85 to 1.10).

## CVD Population

One study of 6975 participants with heart failure compared marine oil ethyl esters (EPA+DHA $0.850-0.882 \mathrm{~g} / \mathrm{d}$ ) with placebo. ${ }^{96}$ The adherence was about $70 \%$ by the end of the 3.9-year study. There was no significant difference in the risk of ischemic stroke between the two groups (OR=1.23; 95\% CI 0.91 to 1.66)

One other study compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester combined with statin with control (statin alone) also did not find significant additive effect of EPA on reducing the risk of ischemic stroke in a subgroup of 942 patients with previous CHD (HR=1.04; 95\% CI 0.67 to 1.62 ). ${ }^{90}$

## Observational Studies

Five studies evaluated the associations between n-3 FA intake or biomarker level and risk of ischemic stroke in healthy adults after 10 to 22 years of followup (Appendix F, Ischemic stroke section; Figure 26). ${ }^{65,73,127,144,145,159,164,186}$ All but one analysis across studies were nonsignificant for an association. All but two analyses across studies were nonsignificant for an association.

## n-3 FA Intake

The five studies all evaluated n-3 FA intake (Atherosclerosis Risk in Communities Study, Cardiovascular Health Study, Health Professional Follow-up Study, MORGEN, Nurses’ Health Study). All found no association with ischemic stroke. This included two studies of ALA intake (Cardiovascular Health Study, MORGEN) in healthy adults after 10 and 12 years of followup (Figure 26, plot \#117), one study of EPA and DHA intake, separately, measured as continuous variables (Atherosclerosis Risk in Communities Study) in healthy adults at 18 years followup, and four studies of combined EPA+DHA intake (Figure 26, plot \#122) in one analysis of all healthy adults (Atherosclerosis Risk in Communities Study), two analyses in men (Health Professionals Follow-up Study, MORGEN), and two analyses in women (Nurses’ Health Study, MORGEN).

By meta-analysis (Table 27), overall there is a statistically significant association between higher marine oil intake and lower risk of ischemic stroke across a median dosage range of 0.025 to $0.6 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.51$; $95 \%$ CI 0.29 to 0.89 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.4 \mathrm{~g} / \mathrm{d}$ ) consistently found a much stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot near or greater than 1). All effect sizes below the knots were statistically significant and all above the knots were nonsignificant. The differences between lower- and higher-dose effect sizes were all statistically significant ( $\mathrm{P}=0.03-0.049$ ). This implies a ceiling effect (where intake above a certain level adds no further benefit). However, it is unclear what the threshold may be, as it may be greater than the highest threshold tested ( $0.4 \mathrm{~g} / \mathrm{d}$ ). The best fit curve was found with a knot at either 0.3 or 0.4 $\mathrm{g} / \mathrm{d}$. The difference between lower-dose and higher-dose ES estimates was statistically significant with a knot at $0.1 \mathrm{~g} / \mathrm{d}$.

## n-3 FA Biomarkers

Three studies evaluated the association between n-3 FA biomarkers and risk of ischemic stroke (Atherosclerosis Risk in Communities Study, Cardiovascular Health Study, MORGEN) in healthy adults.

The Cardiovascular Health Study found a significant association between plasma levels of total n-3 FA (combined) and lower risk of ischemic stroke in healthy adults $\geq 65$ years of age after 16 years of followup (Figure 26, plot \#125).

All three studies found no significant associations between plasma, cholesteryl ester, or phospholipid ALA levels and risk of ischemic stroke in healthy adults after 10, 16, and 22 years of followup (Figure 26, plot \#118).

The Atherosclerosis Risk in Communities Study and the Cardiovascular Health Study found no associations between plasma, cholesteryl ester, or phospholipid EPA levels and risk of ischemic stroke in healthy adults after 16 to 22 years of follow-up (Figure 26, plot \#124).

The same two studies evaluated DHA biomarkers (Figure 26, plot \#119). The Atherosclerosis Risk in Communities Study found that those in the in the highest quintiles of DHA cholesteryl ester and phospholipid levels (separately) had lower risk of ischemic stroke with near-statistical significance ( $\mathrm{P}=0.07$ and 0.08 , respectively). The Cardiovascular Health Study also found the same association across quintiles with plasma DHA with near statistical significance ( $\mathrm{P}=0.052$ ).

The Cardiovascular Health study also evaluated plasma DPA levels and found no significant association with ischemic stroke (Figure 26, plot \#120).

The Atherosclerosis Risk in Communities Study found no significant association with cholesteryl ester or phospholipid EPA+DHA+DPA and ischemic stroke at 22 years of followup (Figure 26, plots \#121 \& 123), and also with phospholipid EPA+DHA at 18 years. MORGEN, however, found a statistically significant association between higher plasma EPA+DHA and ischemic stroke after 10 years.

## Observational Study Subgroup Analyses

The Cardiovascular Health Study found no difference in associations of ALA intake or plasma values and ischemic stroke by amount of fish consumption at baseline or by sex.

## Stroke, Hemorrhagic (Fatal and Nonfatal)

## Randomized Controlled Trials

Two RCTs evaluated hemorrhagic stroke (Table 28). ${ }^{90,96}$ One was conducted in 18,645 participants with dyslipidemia ( $19.5 \%$ with CHD), ${ }^{90}$ and the other was conducted in 6975 participants with heart failure. ${ }^{96}$ Both evaluated n-3 FA ethyl esters. Neither of the trials reported hemorrhagic stroke to be a primary outcomes.

## At-Risk-for-CVD Population

One study compared $1.8 \mathrm{~g} / \mathrm{d}$ purified EPA combined with statin with control (statin alone) to placebo with statin in 18,645 participants with dyslipidemia ( $19.5 \%$ with CHD) ${ }^{90}$ Adherence was verified by local physicians at every clinic visit but the level was not reported. After 5 years of followup, the trial did not find significant difference in the risk of hemorrhagic stroke between participants who were assigned to the EPA+statin group and those in the statin alone group ( $\mathrm{HR}=1.12$; $95 \% \mathrm{CI} 0.91$ to 1.39).

## CVD Population

One study of 6975 participants with heart failure compared marine oil ethyl esters (EPA+DHA $0.850-0.882 \mathrm{~g} / \mathrm{d}$ ) with placebo ${ }^{96}$ The adherence was about $70 \%$ by the end of the 3.9-year study. There was no significant difference in the risk of hemorrhagic stroke between the two groups (OR=1.30; 95\% CI 0.57 to 2.96)

## Observational Studies

Five studies evaluated the associations between n-3 FA intake or biomarker levels and risk of hemorrhagic stroke in healthy adults after 10 to 16 years of followup (Appendix F, Hemorrhagic stroke section; Figure 27). ${ }^{65,73,112,143,145,159, ~} 186$ All but one analysis across studies were nonsignificant for an association.

## n-3 FA Intake

The five studies all evaluated n-3 FA intake (Cardiovascular Health Study, Health Professional Follow-up Study, MORGEN, Nurses’ Health Study, Swedish Mammography Study).

The Cardiovascular Health Study (in adults $\geq 65$ years) and the Swedish Mammography Study in women both found no association between ALA intake and risk of hemorrhagic stroke (Figure 27, plot \#126).

Four studies (Health Professional Follow-up Study, MORGEN, Nurses’ Health Study, Swedish Mammography Study) evaluated EPA+DHA intake (Figure 27, plot \#130). Only MORGEN, in a subgroup of men (<65 years old), found an association between higher EPA + DHA intake and lower risk of hemorrhagic stroke. No such association was found in women in MORGEN or the other three studies.

By meta-analysis (Table 29), overall there is no significant association between marine oil intake and hemorrhagic stroke across a median dosage range of 0.025 to $0.6 \mathrm{~g} / \mathrm{d}$ (effect size per $g / d=0.61 ; 95 \%$ CI 0.34 to 1.11 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found similar associations above and below the knots. At no threshold was the difference in effect sizes statistically significant. The
best fit curve was found with a knot at $0.1 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at $0.5 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.78)$.

## n-3 FA Biomarkers

The Cardiovascular Health Study and MORGEN evaluated plasma n-3 FA and risk of hemorrhagic stroke. Both analyses found no significant associations, including total n-3 FA (combined, Cardiovascular Health Study, Figure 27, plot \#132); ALA (both studies, Figure 27, plot \#126); EPA (Figure 27, plot \#131), DHA (Figure 27, plot \#128), and DPA (Figure 27, plot \#129) (Cardiovascular Health Study); and EPA+DHA (MORGEN).

## Observational Study Subgroup Analyses

The Cardiovascular Health Study found no difference in associations of ALA intake or plasma values and hemorrhagic stroke by amount of fish consumption at baseline or by sex.

## Sudden Cardiac Death

## Randomized Controlled Trials

Nine RCTs evaluated SCD (Table 30). ${ }^{81, ~ 82, ~ 87, ~ 89, ~ 90, ~ 96, ~ 121, ~ 146, ~} 160$ Of these, two studies were conducted in 31,150 participants at risk of CVD (defined as dyslipidemia [19.5\% with CHD] ${ }^{90}$ or with multiple risk factors ${ }^{160}$ ), and eight in a total of 24,463 participants with CVD including diabetes and history of CVD, ${ }^{146}$ arrhythmia, ${ }^{81,82,87} \mathrm{MI},{ }^{89,121}$ CHD or peripheral artery disease, ${ }^{90}$ and heart failure. ${ }^{96}$ One study reported on both at-risk and CVD populations. ${ }^{90}$ No trial reported SCD to be a primary outcome.

## Marine Oil Versus Placebo

Meta-analysis of the nine trials of marine oil yielded a nonsignificant summary HR=1.04 (95\% CI 0.92 to 1.17) (Figure 28). ${ }^{81, ~ 82, ~ 87, ~ 90, ~ 96, ~ 121, ~ 146, ~} 160$

## At-Risk-for-CVD Population

Among people at risk for CVD, one study compared $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester combined with statin with control (statin alone) in 18,645 participants with dyslipidemia, ${ }^{90}$ and one compared marine oil (EPA+DHA) or EPA to placebo in 12,505 participants with multiple risk factors. ${ }^{160}$ The dose of EPA+DHA was at least $0.85 \mathrm{~g} / \mathrm{d}$. Neither study reported adherence level. The durations of followup was 4.6 and 5 years. Both studies found no significant differences in SCD between groups (HR $1.06,95 \%$ CI 0.55 to 2.07 ; OR 1.28 , $95 \%$ CI 0.80 to 1.85). Because the study that combined EPA with statin also included a percentage of patients with CHD, the authors reported the results of a subgroup analysis of patients without previous CHD, though the results were still nonsignificant (HR 1.25; 95\% CI 0.34 to 4.67). ${ }^{90}$

Subgroup meta-analysis yielded a nonsignificant summary HR of 1.17 (95\% CI 0.82 to 1.67) for people at risk for CVD.

## CVD Population

Among people with existing CVD, eight studies compared marine oil (EPA + DHA) to placebo (olive oil or oleic acid sunflower oil), ${ }^{81,82, ~ 87, ~ 89, ~ 90, ~ 96, ~ 121, ~ 146 ~}$ Overall, these trials followed 24,463 people with existing CVD. The EPA+DHA doses ranged from 0.84 to $2.6 \mathrm{~g} / \mathrm{d}$. The duration of followup ranged from 0.8 years to 6.2 years. Compliance, when reported, ranged from 70 to 88 percent. All trials found no significant association, with effect sizes ranging from 0.94 to 3.06 .

The study described above that combined $1.8 \mathrm{~g} / \mathrm{d}$ EPA ethyl ester also reported separate analyses for the patients with CHD and peripheral artery disease at any time. There was no significant additive effect of EPA supplementation on SCD in either group of patients (HR 1.02, $95 \%$ CI 0.47 to 2.19 ; HR 0.19 , $95 \%$ CI 0.01 to 1.33 )..$^{90}$

One study compared two levels of "fish advice" (dietician to advise to increase fish and/or fish oil supplement intake) with no fish advice in a total of 3114 men with MI or angina. ${ }^{89}$ The mean EPA intake estimated by the dietary assessment was 0.45 and $\leq 0.85 \mathrm{~g} / \mathrm{d}$ in the "fish advice" groups, and was 0.11 in the "no fish advice" group. No estimates for DHA intake levels were reported. Compliance was good (fish intake was significantly increased in the "fish advice" groups) based on the dietary assessments. The trial found that, after 9 years of followup, overall, there was no significant difference in SCD between 1109 men with angina who were advised to increase fish intake and 1543 men with angina who were not (adjusted HR 1.43; 95\% CI 0.95 to
2.15; $\mathrm{P}=0.086$ ). The effect was significant in the subgroup of 462 men given advice about taking a fish oil supplement (adjusted HR 1.84, 95\% CI 1.11 to 3.05). There was no significant difference between the two groups (OR 1.19; 95\% CI 0.72 to 1.96). Across the four RCTs of CVD populations, the summary HR was 1.03 ( $95 \%$ CI 0.92 to 1.17).

## RCT Subgroup Analyses

No trial reported a direct within-study subgroup analysis. By meta-regression of the marine oil trials, effect sizes did not vary across studies by dose ( $\mathrm{P}=0.93$ ) or population ( $\mathrm{P}=0.48$ ), but did vary across studies by followup time ( $\mathrm{P}=0.04$ )

## Observational Studies

Four studies evaluated the associations between multiple n-3 FA measures and SCD after about 11 to 18 years of follow-up in mostly healthy adults of varying ages, and also, in one study, women with a history of prior CVD (Appendix F, Sudden coronary death section; Figure 29). ${ }^{60,78,83,84,159,186}$ Analyses and studies found a mix of nonsignificant associations and associations favoring higher n-3 FA quantiles.

## n-3 FA Intake

The Physician's Health Study found no association between total n-3 FA intake (combined) and risk of SCD at 11 years in healthy men (Figure 29, plot \#140). Two studies analyzed ALA intake (Figure 29, plots \#133 \& 134). The Nurses’ Health Study found a significant association between higher ALA intake and lower risk of SCD after 18 years. The Cardiovascular Health Study found no significant association with 16 years of followup. The Japan Public Health Center-Based Study - Cohort I also found no association between EPA+DHA intake and risk of SCD at about 11.5 years (Figure 29, plot \#138).

## n-3 FA Biomarkers

The Cardiovascular Health Study found a significant association between plasma levels of total n-3 FA combined (implicitly ALA, DHA, DPA, and EPA) and lower risk of SCD with 16 years of followup (Figure 29, plot \#141). The Cardiovascular Health Study, however, found no association between plasma ALA level and risk of SCD (Figure 29, plot \#135). Regarding marine oils, this same study found a significant association between plasma DHA (Figure 29, plot \#136) and risk of SCD, but no significant associations with plasma DPA (Figure 29, plot \#137) or EPA (Figure 29, plot \#139).

## Observational Study Subgroup Analyses

In the Nurses' Health Study, the subgroup of women with no history of CVD at baseline had a significant association between higher ALA intake and lower risk of SCD after 18 years; in the smaller subgroup of women with a history of CVD, the effect estimates across quintiles were similar, but not statistically significant. ${ }^{83}$ The Cardiovascular Health Study reported no significant difference (without details) in association of total n-3 FA and SCD between participants with high, low, or no fish consumption and between men and women. ${ }^{186}$

Figure 28. Sudden cardiac death: Randomized trials of marine oils

Random effects model meta-analysis of n-3 FA versus placebo (or no n-3 FA), with subgroup analyses by population. In all meta-analyses, only studies that reported sufficient results data are included.

Abbreviations: $\mathrm{CI}=$ confidence interval, $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DHA}=$ docosahexaenoic acid

Figure 29. n-3 FA associations with sudden cardiac death: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted. $P$ values are the study-reported $P$ value for the trend across quantiles. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White triangles = healthy adults, white squares = healthy males, black squares = healthy females
Abbreviations: ALA = alphalinolenic acid, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HR = hazard ratio, n-3 FA = omega-3 fatty acids, PPFA = plasma polyunsaturated fatty acids.

## Atrial Fibrillation

## Randomized Controlled Trials

Three RCTs evaluated supraventricular tachycardias, specifically AFib. ${ }^{96,133,157}$ All were conducted among people with CVD (Table 31). Specifically, two studies were conducted in a total of 785 people who had previous persistent AFib, ${ }^{133,157}$ and one in 5835 heart failure patients without AFib at study entry. ${ }^{96}$ No study reported AFib to be a primary outcome.

## Marine Oil Versus Placebo

## CVD Population

Among 785 people with previous persistent AFib, two RCTs compared marine oil (EPA+DHA) to placebo (olive oil). ${ }^{133,157}$ The same dose of EPA+DHA ( 0.850 to $0.882 \mathrm{~g} / \mathrm{d}$ ) was used in both studies for a duration of 1 year, but the EPA to DHA ratio was 0.5 in one study and 1.2 in another. Compliance was not reported. Both studies found that EPA+DHA supplementation had no significant effect on the recurrence of AFib (HR 1.28; 95\% CI 0.90 to 1.83; OR $0.52,95 \% 0.26$ to 1.06 ).

Among 5835 heart failure patients without AFib at study entry, one RCT compared marine oil ethyl esters (EPA+DHA) to placebo. ${ }^{96}$ The dose of EPA+DHA was 0.850 to $0.882 \mathrm{~g} / \mathrm{d}$ with a EPA to DHA ratio of 1.2. Compliance was about 70 percent. This study found no significant effect on incidence of AFib comparing EPA+DHA ethyl esters to placebo after a mean 3.9 years of followup (HR $1.1095 \%$ CI 0.96 to 1.25 ). ${ }^{96}$

## RCT Subgroup Analyses

Two RCTs reported subgroup analysis for AFib (Table 32). In one trial of AFib recurrence in people with a history of persistent AFib, ${ }^{157}$ no differences in effect were found between subgroups based on sex, age (at a threshold of 60 years), or duration of prior AFib (at a threshold of 48 hours). In the trial of incident AFib (history of heart failure), ${ }^{96}$ no differences in effect were found between subgroups based on age (threshold 70 years), left ventricular ejection fraction (threshold 40\%), ischemic versus nonischemic heart failure, New York Heart Association class (I\&II vs. III\&IV), diabetes, total cholesterol ( $200 \mathrm{mg} / \mathrm{dL}$ threshold), glomerular filtration rate ( $60 \mathrm{~mL} / \mathrm{min}$ threshold), or fish intake ( 2 servings per week threshold).

## Observational Studies

Five studies evaluated the associations between multiple n-3 FA measures and supraventricular tachycardias (specifically AFib) after 6.4 to 18 years of followup in healthy adults (mostly over age 50 or 65 years) (Appendix F, Atrial fibrillation section; Figure 30). ${ }^{79,86 \text {, }}$ 110, 111, 140,158 Most specific analyses found no significant association and the three studies with significant associations were inconsistent.

## n-3 FA Intake

Four studies evaluated n-3 FA intake. The Cardiovascular Health Study found no significant association with ALA intake (Figure 30, plot \#142), overall and, separately, in men and women. The other three studies (Women’s Health Initiative, Rotterdam, and the Diet, Cancer, Health study) evaluated marine oil (EPA+DHA $\pm$ DPA) intake (Figure 30, plot \#148).

Over a relatively low and narrow range of marine oil intake (less than about $0.3 \mathrm{~g} / \mathrm{d}$ ), the Women's Health Initiative and Rotterdam studies found no significant association. In contrast, the Diet, Cancer, Health study found that after a mean of 8.1 years, higher EPA+DHA+DPA intake, particularly in the quintile with median intake of $1.3 \mathrm{~g} / \mathrm{d}$, was associated with lower risk of AFib in healthy women (age 50 to 64 years).

## n-3 FA Biomarkers

The Cardiovascular Health Study and the Kuopio Ischemic Heart Disease Risk Factor Study evaluated biomarkers. The Cardiovascular Health Study found significantly lower risks of AFib (after 14 years) with higher plasma levels of total n-3 FA combined (not plotted because median quantile values not reported), and DHA (Figure 30, plot \#144) in healthy adults at least 65 years of age. No significant associations were found with plasma ALA (Figure 30, plot \#143), DPA (Figure 30, plot \#146), or EPA (Figure 30, plot \#150). The Kupio study found statistically significant associations for both higher serum fatty acid combined EPA+DHA+DPA (Figure 30, plot \#149) and higher serum fatty acid DHA (plot \#145) with lower risk of AFib at a mean 17.7 years, but no significant associations for serum fatty acid EPA (Figure 30, plot \#151) or DPA (Figure 30, plot \#147).

## Observational Study Subgroup Analyses

In the Cardiovascular Health Study, no differences were found (in a lack of association) for either plasma levels or intake of ALA and AFib between men and women.

Figure 30. n-3 FA associations with atrial fibrillation: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted. $P$ values are the study-reported $P$ value for the trend across quantiles. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White triangles = healthy adults, white squares = healthy males, black squares = healthy females
Abbreviations: ALA = alphalinolenic acid, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HR = hazard ratio, n-3 FA = omega-3 fatty acids, PPFA = plasma polyunsaturated fatty acids.

## Ventricular Arrhythmia

## Randomized Controlled Trials

One 2-by-2 factorial study evaluated ventricular arrhythmia, described as "ventricular arrhythmia-related events (SCD, fatal and nonfatal cardiac arrest, and placement of implantable cardioverter-defibrillators)" (Table 33). ${ }^{193}$ The RCT compared the effects of a margarine
supplemented with EPA+DHA alone ( $0.4 \mathrm{~g} / \mathrm{d}$ ), a combination of both EPA+DHA and ALA margarines, and ALA alone ( $2 \mathrm{~g} / \mathrm{d}$ ) with placebo margarine (oleic acid) in 4837 participants with a history of MI. ${ }^{119}$ (The 2-by-2 factorial trial reported only analyses of EPA+DHA vs. placebo and ALA vs. placebo.) Ventricular arrhythmia was a secondary outcome in the trial.

## Marine Oil Versus Placebo

## CVD Population

The 2-by-2 factorial trial compared $0.4 \mathrm{~g} / \mathrm{d}$ of EPA + DHA in margarine to placebo margarine for 40 months with 90 percent compliance, overall. ${ }^{193}$ The study found no significant effect of marine oil intake on ventricular arrhythmia (HR 0.90; 95\% CI 0.65 to 1.26).

## ALA Versus Placebo

## CVD Population

The 2-by-2 factorial study compared $2 \mathrm{~g} / \mathrm{d}$ ALA in margarine to control margarine. ${ }^{193}$ The trial found no difference in risk of ventricular arrhythmia after 40 months (HR 0.79; 95\% CI 0.57 to 1.10).

## RCT Subgroup Analyses

The same 2-by-2 factorial RCT analyzed subgroups based on history of diabetes (Table 34). ${ }^{193}$ For patients with diabetes, EPA+DHA supplementation resulted in a nonsignificant halving of ventricular arrhythmia risk ( $\mathrm{HR}=0.51, \mathrm{P}=0.09$ ) in contrast to no effect in those without diabetes ( $\mathrm{HR}=1.04, \mathrm{P}=0.83$ ); no test for interaction was reported. The effect of ALA on CVD death was significant in patients with diabetes ( $\mathrm{HR}=0.39, \mathrm{P}=0.02$ ) and nonsignificant for those without diabetes ( $\mathrm{HR}=0.93, \mathrm{P}=0.71$ ).

## Observational Studies

No observational studies evaluated ventricular arrhythmias, per se.

[^1]
## Congestive Heart Failure

## Randomized Controlled Trials

Six RCTs evaluated CHF, all of which evaluated marine oils and had as an endpoint CHF hospitalization (Table 35). ${ }^{51,81,87,146,157,160}$ None of the trials reported CHF to be a primary outcome.

## Marine Oil Versus Placebo

## At-Risk-for-CVD Population

Among 12,505 people with multiple risk factors for CHF, one RCT compared marine oil (EPA + DHA) to placebo for a median duration of 5 years. ${ }^{160}$ The dose of EPA and DHA was at least $0.85 \mathrm{~g} / \mathrm{d}$ (composition of the marine oil was not reported). Adherence was verified by participants’ self-report but the level of adherence was not reported. The trial found a significant risk reduction in CHF hospitalizations in participants who were assigned to marine oil group compared with those in placebo group (HR 0.67 ; $95 \%$ CI 0.52 to 0.87 ).

## CVD Population

Among people with CVD, five RCTs compared marine oil (EPA+DHA) to placebo. ${ }^{51,81,}$
${ }^{87,146,157}$ The RCTs included a total of 13,927 patients. The dose of EPA+DHA ranged from 0.84 $\mathrm{g} /$ d to $6 \mathrm{~g} / \mathrm{d}$; adherence ranged from 76 to 90 percent in the four studies that reported compliance. The duration of followup ranged from 1 to over 6 years. None of the studies found a significant effect on CHF hospitalizations comparing marine oil to placebo, with effect sizes ranging from 0.86 ( $95 \%$ CI 0.26 to 2.81 ) to 1.19 ( $95 \%$ CI 0.52 to 2.73).

## Observational Studies

Eight studies evaluated the associations between intake and biomarkers of n-3 FA and CHF (Appendix F, Congestive heart failure section; Figure 31). ${ }^{86,100,102,112,129,132,148,153,154}$ Definitions of CHF outcomes varied across studies, including incident CHF and CHF hospitalization. One study analyzed only people with a history of MI; the Cohort of Swedish Men also reported a subgroup analysis in people with either diabetes of a history of MI. The remaining analyses were conducted in generally healthy populations. The median followup duration across studies was 9.5 years (range of average followup 4 to 16 years). Studies found a mix of both significant associations between higher n-3 FA intake or biomarker levels and lower risk of CHF and lack of association.

## n-3 FA Intake

Six studies evaluated n-3 FA intake and CHF (Cardiovascular Health Study, Cohort of Swedish Men, Physician's Health Study, Rotterdam, Swedish Mammography Study, Women's Health Initiative). All but one analysis found no associations between n-3 FA intake and CHF.

The four studies assessing ALA intake (Cardiovascular Health Study, Physician's Health Study, Swedish Mammography Study, Women's Health Initiative) found no association with incident CHF or CHF hospitalization or death across 4 to 12 years of followup of healthy adults (Figure 31, plot \#152).

Among the five studies evaluating EPA + DHA or EPA + DHA + DPA intake (Cohort of Swedish Men, Physician's Health Study, Rotterdam, Swedish Mammography Study, Women's Health Initiative), only the Swedish Mammography Study found an association between higher marine oil intake at baseline and CHF (hospitalization or death) in healthy women after 9 years of followup (Figure 31, plot \#157). The Cohort of Swedish Men study, in contrast found no association after 7 years of followup, including in a subgroup analysis of men with a history of MI or diabetes at baseline.

By meta-analysis (Table 36), overall there is a just-significant association between higher marine oil intake and decreased risk of CHF across a median dosage range of 0.014 to $0.71 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.76 ; 95 \%$ CI 0.58 to 1.00 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1). This implies the possibility of a ceiling effect (where intake above a certain level adds no further benefit). However, given that the differences between lower and higher dose ES remained large across the range of testable dose thresholds, the actual ceiling dose threshold may be above the analyzable range (i.e., $>0.5 \mathrm{~g} / \mathrm{d}$ ). At thresholds of 0.1 and $0.2 \mathrm{~g} / \mathrm{d}$, the difference in effect size at lower and higher doses were statistically significant ( P values 0.04 and 0.03 , respectively). But the most significant difference was found at the highest threshold tested, $0.5 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.02)$. The best fit curve was found with the lowest knot tested, $0.1 \mathrm{~g} / \mathrm{d}$.

## n-3 FA Biomarkers

Four studies conducted numerous analyses of n-3 FA biomarkers (Atherosclerosis Risk in Communities Study, Cardiovascular Health Study, Osaka Acute Coronary Insufficiency Study, Physician's Health Study) in healthy adults (3 studies) and adults with a history of MI (Osaka Acute Coronary Insufficiency Study) with 4 or 14 years of followup.

One study (Cardiovascular Health Study) found lower incidence of CHF in adults $\geq 65$ years old after 14 years of followup with higher plasma levels of total n-3 FA combined, but the association was not statistically significant ( $\mathrm{P}=0.062$ ).

Three studies analyzed plasma, cholesteryl ester, and phospholipid ALA (Atherosclerosis Risk in Communities Study, Cardiovascular Health Study, Physician's Health Study) (Figure 31, plots \#153 \& 154). Only the Physicians Health study found an association of lower risk of CHF in men with higher plasma ALA levels after 4 years of followup; the Cardiovascular Health Study found no such association in adults $\geq 65$ years at 14 years of followup and the Atherosclerosis Risk in Communities Study found no association with either cholesteryl ester or phospholipid ALA in younger adults (45-64 years old) also at 14 years of followup.

Three studies analyzed blood, plasma, cholesteryl ester, and phospholipid EPA (Atherosclerosis Risk in Communities Study, Cardiovascular Health Study, Osaka Acute Coronary Insufficiency Study). The studies had heterogeneous findings. The Cardiovascular Health Study found that higher plasma EPA levels were associated with lower risk of CHF in older adults (>65 y) with 14 years of followup (Figure 31, plot \#159), in contrast to a lack of association for DHA (Figure 31, plot \#155). The Osaka Acute Coronary Insufficiency Study also found a significant association between higher blood EPA levels and lower risk of CHF in adults with a history of MI (4 year followup), also in contrast with their finding for DHA (no association). The third study, the Atherosclerosis Risk in Communities Study, found no significant associations with either cholesteryl ester phospholipid DHA and CHF, with no
difference in associations between men and women. These findings were also in contrast to their finding for DHA.

The same three studies analyzed the same DHA biomarkers, with heterogeneous findings. The Cardiovascular Health Study found no association with plasma DHA in healthy older adults ( $\geq 65$ years, 14 year followup) (Figure 31, plot \#155), in contrast with an association found for plasma EPA. The Osaka Acute Coronary Insufficiency Study also found no association with blood DHA in adults with a history of MI (4 year followup), in contrast to an association found for EPA. found a significant difference in association between men and women for both cholesteryl ester and phospholipid DHA.

Only the Cardiovascular Health Study evaluated plasma DPA (Figure 31, plot \#156), in healthy older adults ( $\geq 65$ years) with 14 years of followup. CHF risk was lower in participants with higher plasma DPA levels with near statistical significance ( $\mathrm{P}=0.057$ ).

Two studies analyzed biomarkers for combined marine oils. The Physicians Health Study found no association between plasma EPA+DHA+DPA and CHF risk in healthy men at 4 years (Figure 31, plot \#158). The Atherosclerosis Risk in Communities Study also found no association with cholesteryl ester or phospholipid EPA+DHA+DPA and CHF in healthy men after 14 years. In women, no association was found with cholesteryl ester EPA+DHA+DPA, but higher levels of phospholipid EPA+DHA+DPA were associated with lower CHF risk.

## Observational Study Subgroup Analyses

The Cardiovascular Health Study found no differences in associations between ALA plasma or intake levels and CHF in subgroups based on age, sex, diabetes, or fish consumption (Table 37). ${ }^{148}$

The Osaka Acute Coronary Insufficiency Study conducted multiple subgroup analyses for the associations between blood DHA, blood EPA, and CHF. ${ }^{154}$ For both biomarkers, no significant interaction between subgroups and associations were found for use of angiotensin receptor blocker drugs, use of beta blocker drugs, diabetes, dyslipidemia, hypertension, glomerular filtration function (threshold $=60 \mathrm{~mL} / \mathrm{min}$ ), or hypertriglyceridemia (threshold $=150$ $\mathrm{mg} / \mathrm{dL})$. Statistically significant interactions were found for statin use. In participants taking statins, risk of CHF was not associated with blood DHA (HR=0.74) or EPA (HR=1.45) levels, in contrast with significant associations among participants not taking statins: DHA HR=6.65 ( P interaction $=0.003$ ); EPA HR=6.40 (P interaction $=0.048$ ). Similarly for baseline HDL-c level, a significant interaction was found for blood EPA (P interaction $=0.034$ ) and a nonsignificant interaction for blood DHA (P interaction $=0.096$ ), such that significant associations were seen in participants with low HDL-c ( $<40 \mathrm{mg} / \mathrm{dL}$ ), but not among those with higher HDL-c. Subgroup analyses by sex found a significant interaction (P interaction $=0.008$ ) with blood EPA, but not blood DHA, such that in men there was a significant association between EPA and CHF risk (HR=3.48) but not among women (HR=0.88). Near-significant interactions were found for blood DHA and age ( P interaction $=0.051$, significant association found for those $\geq 65$ years old) and LDL-c (P interaction $=0.068$, significant association found for those with LDL-c $<100 \mathrm{mg} / \mathrm{dL}$ ) (Table 37). No interactions were found for blood EPA.

The Cohort of Swedish Men found no differences in associations of EPA+DHA intake and CHF between men with histories of diabetes or MI and healthy men, or between those who used marine oil supplements or not. ${ }^{102}$

Abbreviations: ALA = alphalinolenic acid, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HR = hazard ratio, n-3 FA = omega-3 fatty acids, PPFA = plasma polyunsaturated fatty acids.

## Hypertension, Incident

## Randomized Controlled Trials

No trial evaluated incident hypertension.

## Observational Studies

Two studies evaluated the associations between intake of multiple n-3 FA or erythrocyte FA and new-onset hypertension after about 13 or 20 years of followup in health adults (Appendix F, Hypertension section; Figure 32). ${ }^{118,124}$ Statistically significant associations were found for younger, but not older, adults (with one exception). The Women's Health Study found that overall total n-3 FA intake and erythrocyte levels were not significantly associated with risk of hypertension (Figure 32, plots \#163 \& 164). Among women 55 to 89 years old at baseline, there were also no significant associations with ALA, DHA, and EPA intake, and with erythrocyte total n-3 FA, ALA, DPA, and DHA levels, but higher erythrocyte EPA levels were
associated with lower hypertension incidence. Among younger women, 39 to 54 years old at baseline, higher DHA intake and higher erythrocyte total n-3 FA, DPA, and DHA levels , but not ALA or EPA levels, were associated with lower hypertension risk. Similarly, the CARDIA study, all in 18 to 30 year old adults, with 20 year followup, higher EPA (Figure 32, plot \#162), DHA (Figure 32, plot \#160), and EPA+DHA+DPA (Figure 32, plot \#161) intake were all significantly associated with lower hypertension incidence.

Figure 32. n-3 FA associations with incident hypertension: Observational studies

Studies that reported associations by continuous exposure (e.g., per g/d intake or per standard deviation) could not be graphed and are omitted. $P$ values are the study-reported $P$ value for the trend across quantiles. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White triangles = healthy adults, black squares = healthy females
Abbreviations: ALA = alphalinolenic acid, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HR = hazard ratio, n-3 FA = omega-3 fatty acids.

## Blood Pressure, Systolic and Diastolic

## Randomized Controlled Trials

Thirty-five RCTs provided data on effect of n-3 FA on systolic blood pressure (BP) (Table 38). Twenty-eight RCTs provided data on effect of n-3 FA on diastolic BP (Table 39). Only five of the trials reported BP to be a primary outcome (Carter 2012, Finnegan 2003, Harrison 2004, Lungershausen 1994, Vasquez 2014); however, Vasquez reported BP to be a secondary outcome in the ClinicalTrials.gov registry. ${ }^{53,75, ~ 80, ~ 147, ~} 174$

## Total n-3 FA Versus Placebo

Two RCTs evaluated supplementation with combined ALA and marine oil (1.2 or 2 g ALA, and 3.6 or 0.4 g EPA+DHA) versus placebo in people with at least one of several risk factors for CVD in one trial ${ }^{180}$ or with CVD in the second trial. ${ }^{119}$ In the at-risk population, at 1 month followup, no differences in systolic or diastolic BP were seen, and the confidence
intervals were wide (systolic net change $=-1.9 \mathrm{mmHg} ; 95 \% \mathrm{CI}-44.7$ to 40.9 ; diastolic net change $=-2.5 \mathrm{mmHg} ; 95 \% \mathrm{CI}-31.3$ to 26.3). In the CVD population, the study found nonsignificant increases in systolic ( 2.3 mmHg ; $95 \% \mathrm{CI}-0.1$ to 4.6 ) and diastolic ( 0.5 mmHg ; $95 \%$ CI -0.7 to 1.7) BPs.

## Marine Oil Versus Placebo

Twenty-nine RCTs compared marine oil versus placebo (or control) and reported on changes in systolic BP in populations of healthy people, those at risk for CVD primarily related to a diagnosis of hypertension, and those with existing CVD (Table 38, Figure 33). ${ }^{48,51,53,55, ~ 61, ~ 62, ~}$ $75,80,85,90,96,99,103,105,115,119,120,123,133,136,146,147,160,173,174,179,180,189,190$ Across the 29 trials, no significant effect was found on systolic BP: summary net change $=0.10 \mathrm{mmHg}(95 \% \mathrm{CI}-0.20$ to 0.40 ).

All but one of these trials also reported diastolic BP. ${ }^{179}$ Across the 28 trials (Table 39, Figure 34), no significant effect was found on diastolic BP: summary net change $=-0.19 \mathrm{mmHg}$ ( $95 \%$ CI -0.43 to 0.05 ).

## Healthy Population

Ten RCTs contributed to a pooled analysis of marine oils (EPA+DHA) against placebo for systolic BP, comprising data from 2,156 healthy individuals with mean baseline systolic BP ranging between 107 to $140.5 \mathrm{mmHg} .{ }^{51,61,75, ~ 85, ~ 136, ~ 147, ~ 173, ~ 174, ~} 189,190$ One study compared both EPA ( $3.8 \mathrm{~g} / \mathrm{d}$ ) and DHA ( $3.6 \mathrm{~g} / \mathrm{d}$ ) ethyl esters, separately, to placebo; ${ }^{61}$ all other evaluated supplements with both EPA+DHA. Marine oil dosage ranged from 0.64 to $3.8 \mathrm{~g} / \mathrm{d}$, and followup duration from 2 months to 1 year. Five studies reported their compliance verification methods (including self-report, food records, pill count, and plasma measurement). All RCTs found no significant effect of EPA+DHA on systolic BP; net systolic BP varied between -3.0 and 1.2 mmHg . The pooled effect size was a nonsignificant $-0.63 \mathrm{mmHg}(95 \% \mathrm{CI}-1.45$ to 0.18$)$.

Ten RCTs contributed to a pooled analysis of marine oils (EPA+DHA) against placebo for diastolic BP, comprising data from 2,240 healthy individuals with mean baseline diastolic BP ranging between 65 to $85.3 \mathrm{mmHg} .^{51,61,75,85,136,147,173,174,189,190}$ RCTs found no significant effect of EPA + DHA on diastolic BP; net diastolic BP varied between -5.7 and 1.9 mmHg . The pooled effect size was a nonsignificant $-0.97 \mathrm{mmHg}(95 \% \mathrm{CI}-1.82$ to -0.13$)$.

## At-Risk-for-CVD Population

Thirteen RCTs contributed to a pooled analysis for systolic BP of marine oils (EPA+DHA) against placebo in those at risk for CVD, comprising data from 45,150 individuals, primarily due to hypertension, with mean baseline systolic BP ranging between 120 and 149 mmHg. ${ }^{53,80,90,99,103,105,115,120,133,146,160,179,180}$ One study compared DHA ( $2 \mathrm{~g} / \mathrm{d}$ ) to placebo; ${ }^{80}$ the rest evaluated supplements with EPA+DHA. Dosage ranged from 0.30 to $6 \mathrm{~g} / \mathrm{d}$, and followup duration from 1 month to 6 years. Eight RCTs reported their compliance verification methods (including self-report, pill count, and plasma measurements). Across trials, the net change in systolic BP varied from -5.3 and 3.8 mmHg , all of which were nonsignificant. The pooled effect size was a nonsignificant $0.22 \mathrm{mmHg}(95 \% \mathrm{CI}-0.14$ to 0.59$)$.

Twelve RCTs contributed to a pooled analysis for diastolic BP of marine oils (EPA+DHA) against placebo in those at risk for CVD, comprising data from 45,072 individuals, primarily due to hypertension, with mean baseline diastolic BP ranging between 76 and 85.5 mmHg . $53,80,90,99,103,105,115,120,133,146,160,180$ Across trials, the net change in diastolic BP varied
from -4.5 and 0.7 mmHg , all of which were nonsignificant. The pooled effect size was a nonsignificant 0.01 mmHg ( $95 \% \mathrm{CI}-0.26$ to 0.27 ).

## CVD Population

Six RCTs contributed to a pooled analysis for systolic BP of marine oils (EPA+DHA) against placebo, comprising data from 11,791 individuals with CVD (mean baseline systolic BP 126 to 133 mmHg ) ${ }^{48,51,62,90,119,123}$ A sixth trial reported only that no significant effect on BP was found. ${ }^{96}$ Dosage ranged from 0.36 to $6 \mathrm{~g} / \mathrm{d}$, and follow-up durations from 1 and 4.7 years. They reported a variety of compliance verification methods (self-report, dietary questionnaire, pill count/audit, and plasma measurements). None of the RCTs found a significant effect of EPA + DHA on systolic BP, with net change ranging from -1 to 0.4 mmHg . The pooled effect size was a nonsignificant $0.17 \mathrm{mmHg}(95 \% \mathrm{CI}-0.48$ to 0.82$)$.

Six RCTs contributed to a pooled analysis for diastolic BP of marine oils (EPA+DHA) against placebo (mean baseline diastolic BP 77 to 83 mmHg ). ${ }^{48,51,62,90,119,123}$ None of the RCTs found a significant effect of EPA + DHA on diastolic BP , with net change ranging from -0.5 to 1.0 mmHg . The pooled effect size was a nonsignificant $-0.11 \mathrm{mmHg}(95 \%$ CI -0.52 to 0.30$)$.

## RCT Subgroup Analyses

Carter 2012 found no differences in effect on BP between two subpopulations of those with prehypertension or normal BP. ${ }^{147}$

By meta-regression, no differences in effect were found based on population (at risk $\mathrm{P}=0.99$ systolic, $\mathrm{P}=0.24$ diastolic; CVD $\mathrm{P}=0.99$ systolic, $\mathrm{P}=0.97$ diastolic), $\mathrm{n}-3$ FA dose ( $\mathrm{P}=0.56$ systolic, $\mathrm{P}=0.42$ diastolic), baseline systolic BP ( $\mathrm{P}=0.91$ systolic) or diastolic BP ( $\mathrm{P}=0.21$ diastolic), or followup duration ( $\mathrm{P}=0.38$ systolic, $\mathrm{P}=0.37$ diastolic).

## ALA Versus Placebo

Five trials compared ALA supplementation to placebo, one in a healthy population, ${ }^{75}$ three in at risk populations, ${ }^{152,167,180}$ and one in a population with CVD (Tables 38 and 39). ${ }^{119}$ The trials evaluated ALA doses ranging from 1.38 to $5.9 \mathrm{~g} / \mathrm{d}$; Jones 2014 evaluated these two doses of ALA versus placebo. ${ }^{180}$ Followup ranged from 1 to 40 months. Compliance was confirmed in four trials and was $>90$ percent in one (Finnegan 2003). All five trials found no significant effect of ALA supplementation on systolic BP, ranging from -7.3 to 5.2 mmHg , or on diastolic BP , ranging from -7.3 to 4.5 mmHg , or on diastolic BP , ranging from -3.9 to 1.0 mmHg , mostly with wide confidence intervals.

## RCT Subgroup Analyses

Rodriguez-Leyva 2013 also found no differences in effect on systolic or diastolic BP in a subpopulation with systolic hypertension ( $>140 \mathrm{mmHg}$ ) compared with the study population as a whole. ${ }^{167}$

## Marine Oil, Comparison of Different Doses

Four trials directly compared different doses of EPA+DHA, three in healthy populations, ${ }^{75,136,190}$ one in an at risk population (Tables 38 and 39). ${ }^{169}$ All found no differences in effects on systolic or diastolic BP between higher and lower EPA+DHA doses ( $1.7 \mathrm{vs} .0 .8 \mathrm{~g} / \mathrm{d}$; 1.8 vs. 0.9 or $0.45 \mathrm{~g} / \mathrm{d} ; 3.4$ vs. $1.7 \mathrm{~g} / \mathrm{d}$ ).

## ALA, Comparison of Different Doses

One trial directly compared different doses of ALA (1.38 and $5.9 \mathrm{~g} / \mathrm{d}$ ) in an at risk population (Tables 38 and 39). ${ }^{180}$ No differences in effects on systolic or diastolic BP were found, with wide confidence intervals, between higher and lower ALA doses ( $5.9 \mathrm{vs} .1 .4 \mathrm{~g} / \mathrm{d}$ ).

## Marine Oils, Comparison of Different Specific n-3 FA

Grimsgaard 1998 directly compared EPA $3.8 \mathrm{~g} / \mathrm{d}$ and DHA $3.6 \mathrm{~g} / \mathrm{d}$ ethyl ester supplementation, finding no differences in effect at 2 months (Tables 38 and 39). ${ }^{61}$ Tatsuno 2013 compared two doses of EPA+DHA ( 3.4 and $1.7 \mathrm{~g} / \mathrm{d}$ ) and EPA $1.8 \mathrm{~g} / \mathrm{d}$ (all ethyl esters); they did not report full data but stated there were no "clinically relevant changes" at 1 year. ${ }^{169}$

## Marine Oil Versus ALA

Finnegan 2003 compared two doses of EPA+DHA (1.7 and $0.8 \mathrm{~g} / \mathrm{d}$ ) and ALA $4.5 \mathrm{~g} / \mathrm{d}$ in a healthy population. ${ }^{75}$ (The study also tested ALA $9 \mathrm{~g} / \mathrm{d}$ but that dose was excluded here because it did not meet eligibility criteria.) The comparisons between either dose of EPA+DHA and ALA found no differences in effect on systolic or diastolic BP at 4 months (Tables 38 and 39). Kromhout 2010 also compared EPA+DHA $0.4 \mathrm{~g} / \mathrm{d}$ to ALA $2 \mathrm{~g} / \mathrm{d}$ in a population with CVD. Neither systolic nor diastolic BP were significantly different between study arms.

## SDA Versus Placebo

Pieters 2015 compared $1.2 \mathrm{~g} / \mathrm{d}$ SDA to placebo in 32 patients at risk for CVD. At 1.5 month followup, no significant differences in change in systolic or diastolic BP were found. ${ }^{188}$

## SDA Versus Marine Oil

Kuhnt 2014 compared $2.0 \mathrm{~g} / \mathrm{d}$ SDA and $1.9 \mathrm{~g} / \mathrm{d}$ EPA+DHA+DPA in 59 healthy people (broken into cohorts based on body mass index and age). At 2 month followup, no significant differences in change in systolic or diastolic BP were found. ${ }^{178}$

## Observational Studies

One study (Guangzhou) evaluated the associations between erythrocyte FA and change in systolic and diastolic BP in healthy men and women (age of 40 to 75 ) after about 3 years (Appendix F, Blood pressure section; Figure 35, Figure 36). Statistically significant decreases in systolic BP were found in those who took higher doses of EPA erythrocyte (Figure 35, plot \#168), DHA erythrocyte (Figure 35, plot \#166) and DPA erythrocyte (Figure 35, plot \#167). Nonsignificant changes in systolic BP were found in those who took higher levels of ALA erythrocyte (Figure 35, plot \#165). Statistically significant decreases in diastolic BP were found in those who took higher doses of EPA erythrocyte (Figure 36, plot \#172), DHA erythrocyte (Figure 36, plot \#170) and DPA erythrocyte (Figure 36, plot \#171). Higher doses of ALA erythrocyte (Figure 36, plot \#169) were not associated with a decrease in diastolic BP.

Abbreviations: ALA = alphalinolenic acid, Ctrl = control, CVD = cardiovascular disease, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, E:D = EPA to DHA ratio, EPA =
eicosapentaenoic acid, F/up = followup, FFQ = food frequency questionnaire, Int = intervention, $\mathrm{n} / \mathrm{N}=$ number with outcome/number analyzed, n6:3=0mega-6 to omega-3 fatty acid ratio, n-3 FA $=$ omega-3 fatty acids, ND = no data, NS = not significant, PMID = PubMed Identification number, RCT = randomized controlled trial.

Figure 33. Systolic blood pressure: Randomized trials of marine oils

Random effects model meta-analysis of n-3 FA versus placebo (or no n-3 FA), with subgroup analyses by population. In all meta-analyses, only studies that reported sufficient results data are included.

Abbreviations: $\mathrm{CI}=$ confidence interval, $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DHA}=$ docosahexaenoic acid, $\mathrm{DPA}=$ docosapentaenoic acid, EPA $=$ eicosapentaenoic acid, n-3 FA = omega-3 fatty acids

Abbreviations: ALA = alphalinolenic acid, Ctrl = control, CVD = cardiovascular disease, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, E:D = EPA to DHA ratio, EPA =
eicosapentaenoic acid, F/up = followup, Int = intervention, $\mathrm{n} / \mathrm{N}=$ number with outcome/number analyzed, n6:3 = omega-6 to omega-3 fatty acid ratio, ND $=$ no data, $\mathrm{NS}=$ not significant, PMID $=$ PubMed Identification number, RCT = randomized controlled trial.

Figure 34. Diastolic blood pressure: Randomized trials of marine oils

Random effects model meta-analysis of n-3 FA versus placebo (or no n-3 FA), with subgroup analyses by population. In all meta-analyses, only studies that reported sufficient results data are included.

Abbreviations: $\mathrm{CI}=$ confidence interval, $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DBP}=$ diastolic blood pressure, DHA = docosahexaenoic acid, DPA $=$ docosapentaenoic acid, EPA = eicosapentaenoic acid, n-3 FA = omega-3 fatty acids, Phet $=\mathrm{P}$ value of chi-squared test of heterogeneity across studies, PMID $=$ PubMed Identification number.

Figure 35. n-3 FA associations with systolic blood pressure: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. P values are the study-reported $P$ value for the trend across quantiles. Where $95 \%$ confidence intervals (vertical lines) are missing, these were not reported in the studies. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White triangles = healthy adults
Abbreviations: ALA = alphalinolenic acid, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, FA = fatty acid, HR = hazard ratio, n-3 FA = omega-3 fatty acids.

Figure 36. n-3 FA associations with diastolic blood pressure: Observational studies

Study (or cohort) level associations between n-3 FA exposure and hazard ratio (HR) for the outcome. P values are the study-reported $P$ value for the trend across quantiles. Where $95 \%$ confidence intervals (vertical lines) are missing, these were not reported in the studies. The $95 \%$ confidence intervals were truncated when $<0.25$ and $>2$.
White triangles = healthy adults
Abbreviations: ALA = alphalinolenic acid, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, FA = fatty acid, $\mathrm{HR}=$ hazard ratio, $\mathrm{n}-3 \mathrm{FA}=$ omega- 3 fatty acids.

## Mean Arterial Pressure

## Randomized Controlled Trials

Four RCTs reported on mean arterial pressure (MAP), all of which evaluated only marine oils (Table 40). ${ }^{61,123,136,147}$ One of the trials reported MAP among its primary outcomes (Carter 2012). ${ }^{147}$

## Marine Oil Versus Placebo

## Healthy Population

Three trials evaluated healthy populations, including the previously described trial that compared EPA $3.8 \mathrm{~g} / \mathrm{d}$ and DHA $3.6 \mathrm{~g} / \mathrm{d}$ ethyl esters to placebo, ${ }^{61}$ the trial of $2.7 \mathrm{~g} / \mathrm{d}$ EPA+DHA in two healthy subgroups (with normotension or prehypertension), ${ }^{147}$ and the comparison of 1.8 $\mathrm{g} / \mathrm{d}, 0.9 \mathrm{~g} / \mathrm{d}$, and $0.45 \mathrm{~g} / \mathrm{d}$ versus placebo. ${ }^{136}$ Followup was either 2 months or 1 year. Baseline MAP ranged from 79 to 92 mmHg . All trials found no significant effect on MAP, with estimates of net change ranging from -1 to 2 mmHg .

## CVD Population

One trial of $0.6 \mathrm{~g} / \mathrm{d}$ EPA+DHA versus placebo (with or without B vitamin) was conducted in 2501 people with a history of CVD. ${ }^{123}$ At 4.7 years, there was no difference in MAP between the two groups.

## RCT Subgroup Analyses

Carter 2012 found no differences in effect between two subpopulations of those with prehypertension or normal BP. ${ }^{147}$

## Marine Oil, Comparison of Different Doses

One trial directly compared different doses of EPA+DHA in healthy populations. ${ }^{136}$ Sanders 2011 found no differences in effects on MAP between higher and lower EPA+DHA doses (1.8, 0.9 or $0.45 \mathrm{~g} / \mathrm{d}$ ).

## Marine Oils, Comparison of Different Specific n-3 FA

Grimsgaard 1998 directly compared EPA 3.8 g/d and DHA 3.6 g/d ethyl ester supplementation, finding no differences in effect at 2 months. ${ }^{61}$

## Observational Studies

Observational studies did not evaluate MAP.

## Low Density Lipoprotein Cholesterol

## Randomized Controlled Trials

Forty-five RCTs provided data on effect of n-3 FA on LDL-c (Table 41) ${ }^{46,51,53,56,58, ~ 61, ~}$ $62,70,75,76,80,85,90,94,96,97,99,103,105,107,116,119-121,128,136,146,151,152,156,160,161,166,167,169,173,174,177,178$, 180, 184, 187-189, 194 Only six of the trials reported LDL-c among their primary outcomes (Caslake 2008, Damsgaard 2008, Lungershausen 1994, Olano-Martin 2010, Rasmussen 2006, Sirtori 1997). ${ }^{53,58,85,94, ~ 97, ~} 107$

## Total n-3 FA Versus Placebo

Two trials compared total n-3 FA (ALA+EPA+DHA) versus placebo, following 2708 patients for 1 and 40 months; one in people at increased risk for CVD, ${ }^{180}$ one in people with CVD. ${ }^{119}$ Baseline LDL-c measurements were 100 and $129 \mathrm{mg} / \mathrm{dL}$. Compliance was measured in all studies, but not reported. One trial in an at risk population found a statistically significant increase in LDL-c with combined ALA $1.2 \mathrm{~g} / \mathrm{d}$ (canola oil) and EPA+DHA+DPA (11.3 mg/dL; $95 \%$ CI 1.7 to 20.8). ${ }^{180}$. The trial in a CVD population found no significant effect on LDL-c with ALA $2 \mathrm{~g} / \mathrm{d}$ and EPA+DHA $0.4 \mathrm{~g} / \mathrm{d} .{ }^{119}$

## Marine Oil Versus Placebo

Thirty-nine trials evaluated the effect of marine oils versus placebo on LDL-c. ${ }^{46,51,53,56,}$ $58,61,62,70,75,76,80,85,90,94,96,97,99,103,105,107,116,119-121,128,136,146,151,156,160,166,173,174,177,180,184,187$, 189, 194

Doses of EPA + DHA $\pm$ DPA ranged from 0.3 to $6 \mathrm{~g} / \mathrm{d}$ (median $2.4 \mathrm{~g} / \mathrm{d}$ ) and followup time ranged from 1 month to 6 years (median 3 months). Across populations, the meta-analyzed summary net difference in LDL-c with EPA+DHA versus placebo (or equivalent) was a statistically significant $1.98 \mathrm{mg} / \mathrm{dL}$ (95\% CI 0.38 to 3.58) (Figure 37).

## Healthy Population

Sixteen of the trials of marine oils versus placebo were conducted in healthy populations, comprising data from 3,749 individuals with mean baseline LDL-c ranging from 100 to 218 and followup duration from 1 to 12 months. ${ }^{61,75, ~ 80, ~ 85, ~ 94, ~ 97, ~ 103, ~ 107, ~ 128, ~ 136, ~ 146, ~ 173, ~} 174,187,189$ Two studies compared both purified EPA ( 3.3 and $3.8 \mathrm{~g} / \mathrm{d}$ ) and DHA ( 3.6 and $3.7 \mathrm{~g} / \mathrm{d}$ ) ethyl esters, separately, to placebo; ${ }^{61,107}$ all other evaluated supplements with both EPA+DHA, with doses ranging from 0.45 to $6 \mathrm{~g} / \mathrm{d}$. Compliance was verified with pill counts, dietary records, or biomarker confirmation in six of the studies. All but one RCT found no significant effect of EPA+DHA on LDL-c; net LDL-c varied between -5.4 and $12.7 \mathrm{mg} / \mathrm{dL}$. The pooled effect size was a nonsignificant $2.70 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.64$ to 6.03$)$.

## At-Risk-for-CVD Population

Twenty of the trials were conducted in populations at increased risk of CVD, comprising data from 48,762 individuals with mean baseline LDL-c ranging from 78.2 to 191.1 and followup duration from 1 month to 6 years. ${ }^{46,53,58,76,80,90,99,103, ~ 105, ~ 116, ~ 120, ~ 146, ~ 156, ~ 160, ~ 166, ~ 177, ~ 180, ~ 187, ~}$ ${ }^{194,195}$ One study compared purified DHA ( $2 \mathrm{~g} / \mathrm{d}$ ) to placebo; ${ }^{80}$ all other evaluated supplements with both EPA+DHA, with doses ranging from 0.3 to $6 \mathrm{~g} / \mathrm{d}$. Compliance was verified with pill counts, dietary records, self-report or biomarker confirmation in 11 of the studies. All but two RCTs found no significant effect of EPA+DHA on LDL-c; net change LDL-c varied between
-27.4 and $10.4 \mathrm{mg} / \mathrm{dL}$. The pooled effect size was a nonsignificant $2.34 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.82$ to 5.49).

## CVD Population

Eight of the trials were conducted in people with CVD, comprising data from 28,699 individuals with mean baseline LDL-c ranging from 99 to $181 \mathrm{mg} / \mathrm{dL}$ and followup duration from 9 months to 4.6 years. ${ }^{51,56,62,70,90,96,119,121}$ Compliance was verified in four of the studies, by pill count or equivalent. All trials found no significant effect on LDL-c; net change LDL-c varied from -0.8 to $5.8 \mathrm{mg} / \mathrm{dL}$. The pooled effect size was a nonsignificant $1.92 \mathrm{mg} / \mathrm{dL}(95 \%$ CI -1.05 to 4.89 ).

## RCT Subgroup Analyses

Eight of the trials compared effects of marine oils in different subgroups of participants; five reported statin vs no statin, ${ }^{46,99,119,128,156}$ one with or without vitamin C, ${ }^{76}$ one men vs women, ${ }^{97}$ one older vs younger age, ${ }^{97}$ and one saturated FA diet vs monosaturated FA diet. ${ }^{85}$ All found (or reported) no significant interactions (differences in effect) by subgroup or cointervention.

By meta-regression, across studies there were no significant differences in effect (interactions) by LDL-c baseline ( $\mathrm{P}=0.93$ ), n-3 FA dose ( $\mathrm{P}=0.93$ ), followup duration ( $\mathrm{P}=0.29$ ), or population (at risk $\mathrm{P}=0.51$; CVD $\mathrm{P}=0.98$ ).

## Marine Oil, Comparison of Different Doses

Ten RCTs directly compared different doses of marine oils (EPA+DHA), ${ }^{75,97,136,151,161,}$ 166, 169, 177, 184, 194, 195 between 0.9 and $4 \mathrm{~g} / \mathrm{d}$. All comparisons were nonsignificant for effect on LDL-c, with estimates of differences ranging from $-11.6 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-22.5$ to $-0.66 ; 1.8$ vs. $0.45 \mathrm{~g} / \mathrm{d}$ ) to $14 \mathrm{mg} / \mathrm{dL}(95 \%$ CI 0.4 to 27.7; 1.7 vs. $0.8 \mathrm{~g} / \mathrm{d}$ ).

## ALA Versus Placebo

Five trials compared ALA to placebo (or equivalent) in a healthy population, ${ }^{75}$ at-risk populations, ${ }^{152,167,180}$ and a population with CVD. ${ }^{119}$ In total, there were 5,452 participants followed for 1 to 40 months, with ALA doses of 0.4 to $5.9 \mathrm{~g} / \mathrm{d}$. None of the trials found a significant effect of ALA on LDL-c, with net changes ranging from -1.2 to $14.5 \mathrm{mg} / \mathrm{dL}$, mostly with wide confidence intervals.

## ALA, Comparison of Different Doses

One trial compared ALA 5.9 and $1.4 \mathrm{~g} / \mathrm{d}$ and found no difference in effect on LDL-c with wide confidence intervals ( $1.3 \mathrm{mg} / \mathrm{dL} ; 95 \% \mathrm{CI}-8.3$ to 11 ). ${ }^{180}$

## Comparison of Different Specific n-3 FA

Two trials directly compared EPA ( 3.8 or $3.3 \mathrm{~g} / \mathrm{d}$ ) to DHA ( 3.6 or $3.7 \mathrm{~g} / \mathrm{d}$ ), ${ }^{61,107}$ one of which evaluated EPA and DHA ethyl esters, ${ }^{61}$ the other evaluated EPA- and DHA-enriched oils. ${ }^{107}$ Both found larger, but nonsignificant, relative reductions in LDL-C with EPA than DHA (net difference -5.8 [ $95 \% \mathrm{CI}-11.7$ to 0.1 ]; -6.2 [95\% CI -21.8 to 9.4$]$ ). One trial compared two doses of EPA+DHA ( 3.4 and $1.7 \mathrm{~g} / \mathrm{d}$ ) to EPA $1.8 \mathrm{~g} / \mathrm{d}$ (all ethyl esters), ${ }^{169}$ with no significant differences between marine oil formulations. Two trials compared EPA+DHA to ALA, one comparing two doses of EPA+DHA ( 1.7 and $0.8 \mathrm{~g} / \mathrm{d}$ ) to ALA $4.5 \mathrm{~g} / \mathrm{d},{ }^{75}$ one comparing $0.4 \mathrm{~g} / \mathrm{d}$

EPA+DHA to $2 \mathrm{~g} / \mathrm{d}$ ALA. ${ }^{119}$ All comparisons were reported as nonsignificant, but the comparison of the higher dose marine oil in Finnegan 2003 found a large relative increase in LDL-c with a significant estimated CI ( $14.0 \mathrm{mg} / \mathrm{dL}$; 95\% CI 0.4 to 27.7).

## SDA Versus Placebo

Pieters 2015 compared 1.2 g/d SDA to placebo in 32 patients at risk for CVD. At 1.5 month followup, no significant differences in change in LDL-c were found. ${ }^{188}$

## SDA Versus Marine Oil

Kuhnt 2014 compared 2.0 g/d SDA and 1.9 g/d EPA+DHA+DPA in 59 healthy people (broken into cohorts based on body mass index and age). At 2 month followup, no significant differences in change in LDL-c ratios were found. ${ }^{178}$

## Observational Studies

Observational studies did not evaluate LDL-c.

[^2]Figure 37. Low density lipoprotein cholesterol: Randomized trials of marine oils

Random effects model meta-analysis of n-3 FA versus placebo (or no n-3 FA), with subgroup analyses by population. In all meta-analyses, only studies that reported sufficient results data are included.

Abbreviations: $\mathrm{CI}=$ confidence interval, $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DHA}=$ docosahexaenoic acid, $\mathrm{EPA}=$ eicosapentaenoic acid, $\mathrm{LDL}=$ low density lipoprotein, n-3 FA = omega-3 fatty acids, Phet = P value of chi-squared test of heterogeneity across studies, PMID = PubMed Identification number.

## High Density Lipoprotein Cholesterol

## Randomized Controlled Trials

Forty-six RCTs provided data on effect of n-3 FA on HDL-c (Table 42). ${ }^{46,48,51,53,55,56,}$ $58,61,62,67,70,75,76,80,90,94,96,97,99,103,105,107,115,116,119,120,128,136,146,151,152,156,160,167,173,174,177-180$, 184, 187-189, 194 Only four of the trials reported HDL-c among their primary outcomes (Damsgaard 2008, Harrison 2004, Lungershausen 1994, Sirtori 1997). ${ }^{53,58, ~ 80,94}$

## Total n-3 FA Versus Placebo

Two trials compared total n-3 FA (ALA+EPA+DHA) versus placebo, following 2708 patients for 1 and 40 months; one in people at increased risk for CVD, ${ }^{180}$ one in people with CVD. ${ }^{119}$ Baseline HDL-c measurements were 47 and $50 \mathrm{mg} / \mathrm{dL}$. Compliance was measured in both studies, but not reported. The trial in an at risk population found a statistically significant increase in HDL-c with combined ALA $1.2 \mathrm{~g} / \mathrm{d}$ (canola oil) and EPA+DHA+DPA $5 \mathrm{~g} / \mathrm{d}$ ( 3.9 $\mathrm{mg} / \mathrm{dL} ; 95 \%$ CI 1.5 to 6.2 ). ${ }^{180}$ The trial in a CVD population found no significant effect on HDLc with ALA $2 \mathrm{~g} / \mathrm{d}$ and EPA+DHA $0.4 \mathrm{~g} / \mathrm{d}$. ${ }^{119}$

## Marine Oil Versus Placebo

Thirty-four trials evaluated the effect of marine oils versus placebo on HDL-c. ${ }^{46,51,53,56,}$ $58,61,62,67,70,75,76,80,94,96,97,99,103,105,107,115,116,119,120,128,146,156,160,166,173,177,179,180,194,195$ $\qquad$ of EPA+DHA ranged from 0.3 to $6 \mathrm{~g} / \mathrm{d}$ (median $6 \mathrm{~g} / \mathrm{d}$ ) and followup time ranged from 1 month to 6 years (median 3 months). Across populations, by meta-analysis (Figure 38), the summary net difference in HDL-c with EPA+DHA versus placebo (or equivalent) was a statistically significant, but small, $0.88 \mathrm{mg} / \mathrm{dL}$ ( $95 \%$ CI 0.20 to 1.57).

## Healthy Population

Thirteen of the trials of marine oils versus placebo were conducted in healthy populations, comprising data from 3,755 individuals with mean baseline HDL-c ranging from 45 to $57.9 \mathrm{mg} / \mathrm{dL}$ and followup duration from 1 to 12 months. ${ }^{55}, 61,75,80,94,97,107,128,136,173,174,187,189$
Two studies compared both EPA ( 3.3 and $3.8 \mathrm{~g} / \mathrm{d}$ ) and DHA ( 3.6 and $3.7 \mathrm{~g} / \mathrm{d}$ ), separately, to placebo, one of which evaluated EPA and DHA ethyl esters, ${ }^{61}$, one of which evaluated EPA- and DHA-enriched oils. ${ }^{107}$ All other evaluated supplements with both EPA+DHA, with doses ranging from 0.45 to $3.8 \mathrm{~g} / \mathrm{d}$. Compliance was verified with pill counts, dietary records, or biomarker confirmation in six of the studies. One trial found significant net increases in HDL-c with marine oil (at two different doses, 0.7 and $1.8 \mathrm{~g} / \mathrm{d}$ ) of $2.3 \mathrm{mg} / \mathrm{dL}(95 \%$ CI 0.2 to 4.5). One study, of DHA $3.6 \mathrm{~g} / \mathrm{d}$ alone, found a significant net increase in HDL-c ( $2.7 \mathrm{mg} / \mathrm{dL}$; 95\% CI 1.2 to 4.2), but not with EPA $3.8 \mathrm{~g} / \mathrm{d}$. The pooled effect size was nonsignificant: $0.87 \mathrm{mg} / \mathrm{dL}$ ( $95 \%$ CI -0.11 to 1.84 ) (Figure 38). ${ }^{187}$

## At-Risk-for-CVD Population

Twenty-two of the trials were conducted in populations at increased risk of CVD, comprising data from 48,293 individuals with mean baseline HDL-c ranging from 28.7 to 65.6 $\mathrm{mg} / \mathrm{dL}$ and followup duration from 1 month to 6 years. ${ }^{46,53,58,76,80,90,99,103,105,115,116,120,146,156,}$ $160,166,177,179,180,187,194,195$ One study compared DHA ( $2 \mathrm{~g} / \mathrm{d}$ ) to placebo; ${ }^{80}$ all other evaluated supplements with both EPA+DHA, with doses ranging from 0.3 to $6 \mathrm{~g} / \mathrm{d}$. Compliance was
verified with pill counts, dietary records, self-report or biomarker confirmation in 11 of the studies. Thirteen of the 17 trials found no significant effects of EPA+DHA on HDL-c; net change HDL-c varied between 14.9 and $9.3 \mathrm{mg} / \mathrm{dL}$. The pooled effect size was nonsignificant, $0.81 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.41$ to 2.03 ) (Figure 38).

## CVD Population

Nine of the trials were conducted in people with CVD, comprising data from 27,080 individuals with mean baseline HDL-c ranging from 39 to $50.2 \mathrm{mg} / \mathrm{dL}$ and followup duration from 9 months to 6 years. ${ }^{48,51,56,62,67,70,90,96,119}$ Doses ranged from $0.36 \mathrm{~g} / \mathrm{d}$ to $6 \mathrm{~g} / \mathrm{d}$; compliance was verified in four of the studies, by pill count or equivalent. Two of the nine trials found significant net increases in HDL-c, but net change HDL-c varied from -1.2 to $3.1 \mathrm{mg} / \mathrm{dL}$. The pooled effect size was a statistically significant, but small, $0.72 \mathrm{mg} / \mathrm{dL}$ ( $95 \%$ CI 0.16 to 1.28) (Figure 38).

## RCT Subgroup Analyses

Eight of the trials compared effects of marine oils in different subgroups of participants; three reported statin vs no statin, ${ }^{46,99,156}$ one with or without vitamin C, ${ }^{76}$ two men vs women, ${ }^{97}$, ${ }^{179}$ one older vs younger age, ${ }^{97}$ and one impaired glucose tolerance versus normoglycemia. ${ }^{58}$ One study found a larger effect of marine oil among participants who were also exercising (men 9.3 $\mathrm{mg} / \mathrm{dL}$; women $7.6 \mathrm{mg} / \mathrm{dL}$ ) than in groups not exercising (men $1.7 \mathrm{mg} / \mathrm{dL}$; women $-0.9 \mathrm{mg} / \mathrm{dL}$ ), although it was unclear whether these differences were significantly different from each other. ${ }^{179}$ Another study found a small but significantly different effect ( $\mathrm{P}<0.05$ ) of marine oil $2.6 \mathrm{~g} / \mathrm{d}$ in men with impaired glucose tolerance ( $0.8 \mathrm{mg} / \mathrm{dL}$ ) than those with normoglycemia $(0.4 \mathrm{mg} / \mathrm{dL}) .{ }^{58}$ Other subgroup analyses found no differences in effect between subgroups.

By meta-regression, across studies there were no significant differences in effect (interactions) by HDL-c baseline ( $\mathrm{P}=0.16$ ), $\mathrm{n}-3 \mathrm{FA}$ dose ( $\mathrm{P}=0.62$ ), followup duration ( $\mathrm{P}=0.24$ ), or population (at risk $\mathrm{P}=0.29$; $\mathrm{CVD} \mathrm{P}=0.82$ ).

## Marine Oil, Comparison of Different Doses

Eight RCTs directly compared different doses of marine oils (EPA+DHA), ${ }^{75,97,136,151, ~ 161,}$ 169, 177, 194 between 0.9 and $4 \mathrm{~g} / \mathrm{d}$. All comparisons were nonsignificant for effect on HDL-c, with estimates of differences ranging from $-3.9 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-9.3$ to $1.6 ; 0.9 \mathrm{vs} .0 .45 \mathrm{~g} / \mathrm{d})$ to 3.9 $\mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-1.6$ to $9.3 ; 1.8$ vs. $0.9 \mathrm{~g} / \mathrm{d})$.

## ALA Versus Placebo

Five trials compared ALA versus placebo (or equivalent) in 661 people at increased risk of CVD and one trial of 4837 people with CVD. ${ }^{75,119,152,167,180}$ ALA doses ranged from 1.4 to $5.9 \mathrm{~g} / \mathrm{d}$ and followup ranged from 1 to 40 months. All studies assessed compliance. Effect on HDL-c ranged from -0.3 to $2.3 \mathrm{mg} / \mathrm{d}$, all but one study were statistically nonsignificant.

## ALA, Comparison of Different Doses

One trial compared ALA 5.9 and $1.4 \mathrm{~g} / \mathrm{d}$ and found no difference in effect on HDL-c. ${ }^{180}$

## Comparison of Different Specific n-3 FA

Two trials directly compared EPA ( 3.8 or $3.3 \mathrm{~g} / \mathrm{d}$ ) to DHA ( 3.6 or $3.7 \mathrm{~g} / \mathrm{d}$ ), one of which evaluated EPA and DHA ethyl esters, ${ }^{61}$ one of which evaluated EPA- and DHA-enriched oils. ${ }^{107}$

Both found similar (nonsignificant) effects on HDL-c with EPA or DHA. One trial compared two doses of EPA+DHA ( 3.4 and $1.7 \mathrm{~g} / \mathrm{d}$ ) to EPA $1.8 \mathrm{~g} / \mathrm{d}$ (all ethyl esters), ${ }^{169}$ with no differences between marine oil formulations. Two trials compared EPA+DHA to ALA. One compared two doses of EPA+DHA ( 1.7 and $0.8 \mathrm{~g} / \mathrm{d}$ ) to ALA $4.5 \mathrm{~g} / \mathrm{d} ;{ }^{75}$ both comparisons were nonsignificant with similar net differences ( 1.5 and $2.3 \mathrm{mg} / \mathrm{dL}$ ). The second trial compared EPA+DHA $0.2 \mathrm{~g} / \mathrm{d}$ to ALA $2 \mathrm{~g} / \mathrm{d}$; the study did not report a significant difference, but a calculated net difference was statistically significant favoring EPA+DHA (net difference $1.9 \mathrm{mg} / \mathrm{dL} ; 95 \%$ CI 0.9 to 3.0). ${ }^{119}$

## SDA Versus Placebo

Pieters 2015 compared 1.2 g/d SDA to placebo in 32 patients at risk for CVD. At 1.5 month followup, no significant differences in change in HDL-c were found. ${ }^{188}$

## SDA Versus Marine Oil

Kuhnt 2014 compared 2.0 g/d SDA and 1.9 g/d EPA+DHA+DPA in 59 healthy people (broken into cohorts based on body mass index and age). At 2 month followup, no significant differences in change in HDL-c were found. ${ }^{178}$

## Observational Studies

Observational studies did not evaluate HDL-c.

Abbreviations: ALA = alphalinolenic acid, Ctrl = control, CVD = cardiovascular disease, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, E:D = EPA to DHA ratio, EPA =
eicosapentaenoic acid, F/up = followup, FA = fatty acid(s), FFQ = food frequency questionnaire, Int = intervention, n/N = number with outcome/number analyzed, n6:3 = omega-6 to omega-3 fatty acid ratio, n-3 FA = omega-3 fatty acids, ND = no data, NS = not significant, $\mathrm{PMID}=$ PubMed Identification number, $\mathrm{RCT}=$ randomized controlled trial.

Figure 38. High density lipoprotein cholesterol: Randomized trials of marine oils

Random effects model meta-analysis of n-3 FA versus placebo (or no n-3 FA), with subgroup analyses by population. In all meta-analyses, only studies that reported sufficient results data are included.

Abbreviations: $\mathrm{CI}=$ confidence interval, $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DHA}=$ docosahexaenoic acid, $\mathrm{EPA}=$ eicosapentaenoic acid, $\mathrm{HDL}=$ high density lipoprotein cholesterol, n-3 FA = omega-3 fatty acid, $\mathrm{Phet}=\mathrm{P}$ value of chi-squared test of heterogeneity across studies, PM ID $=\mathrm{PubMed}$ Identification number.

## Triglycerides

## Randomized Controlled Trials

Forty-six RCTs provided data on effect of n-3 FA on Tg (Table 43). ${ }^{46,51,53,56,58, ~ 61, ~ 62, ~ 67, ~}$ $70,75,76,90,94,96,97,99,103,105,107,115,116,119-121,125,128,136,146,150-152,156,160,167,169,173,174,177,178,180,184$, ${ }^{187-189,194}$ Compared with other outcomes, a relatively large number of trials, 11, but still a minority, reported Tg among their primary outcome (Brinton 2013, Caslake 2008, Damsgaard 2008, Kastelein 2014, Lungershausen 1994, Pieters 2015, Ras 2014, Rauch 2010, Shidfar 2003, Sirtori 1997, Vazquez 2014); however, Rauch 2010 reported Tg to be a secondary outcome in the ClinicalTrials.gov registry.

## Total n-3 FA Versus Placebo

Two trials compared total n-3 FA (ALA+EPA+DHA) versus placebo, following 2708 patients for 1 and 40 months; one in people at increased risk for CVD, ${ }^{180}$ one in people with CVD. ${ }^{119}$ Baseline Tg measurements were 147.8 and $150 \mathrm{mg} / \mathrm{dL}$. Compliance was measured in both studies, but not reported. The trial in an at risk population found a statistically significant decrease in Tg with combined ALA $1.2 \mathrm{~g} / \mathrm{d}$ (canola oil) and EPA+DHA+DPA $5 \mathrm{~g} / \mathrm{d}(-27 \mathrm{mg} / \mathrm{dL}$; $95 \%$ CI -37.5 to -7.6 ). ${ }^{180}$ The trial in a CVD population found no significant effect on Tg with ALA $2 \mathrm{~g} / \mathrm{d}$ and EPA+DHA $0.4 \mathrm{~g} / \mathrm{d} .{ }^{119}$

## Marine Oil Versus Placebo

Forty-one trials evaluated the effect of marine oils versus placebo on Tg. ${ }^{46,51,53,56,58,61, ~ 62,}$ $67,70,75,76,90,94,96,97,99,103,105,107,115,116,119-121,125,128,136,146,150,151,156,160,166,173,174,177,180,187,189$, ${ }^{194}$ Doses of EPA+DHA $\pm$ DPA ranged from 0.3 to $6 \mathrm{~g} / \mathrm{d}$ (median $2.4 \mathrm{~g} / \mathrm{d}$ ) and followup time ranged from 1 month to 6 years (median 3 months). All but two studies found net decreases in Tg with EPA+DHA. Across populations, the summary net difference in Tg with EPA+DHA versus placebo (or equivalent) was a statistically significant $-24 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-31$ to -18 ) among studies reporting sufficient data to be included in meta-analysis. As will be described below, net change Tg varied across studies by mean baseline Tg and, possibly, by EPA+DHA dose, but did not vary significantly by population (Figure 39).

## Healthy Population

Fourteen of the trials were conducted in 3,560 generally healthy participants. ${ }^{61,75,94,97,103,}$ 107, 128, 136, 146, 151, 173, $174,187,189$ Two of the trials evaluated both purified EPA and DHA separately ( 3.3 to $3.8 \mathrm{~g} / \mathrm{d}$ ); the rest evaluated EPA+DHA ( 0.45 to $3.1 \mathrm{~g} / \mathrm{d}$ ). Followup ranged from 1 to 12 months. Four studies evaluated compliance with pill count or weighed food records. Baseline Tg ranged from 80 to $188 \mathrm{mg} / \mathrm{dL}$. Net difference between marine oil and placebo varied widely across studies from -42 to $7.7 \mathrm{mg} / \mathrm{dL}$. The pooled effect size was a significant $-13.2 \mathrm{mg} / \mathrm{dL}$ ( $95 \% \mathrm{CI}-20.2$ to -6.2 ) (Figure 39).

## At-Risk-for-CVD Population

Twenty-three trials compared EPA+DHA to placebo (or equivalent) in 48,648 people at increased risk of CVD. ${ }^{46,53,56,58,76,90,99,103, ~ 105, ~ 115, ~ 116, ~ 119, ~ 120, ~ 146, ~ 150, ~ 156, ~ 160, ~ 166, ~ 177, ~ 180, ~ 187, ~ 194, ~} 195$ EPA+DHA dosages ranged from 0.3 to $5 \mathrm{~g} / \mathrm{d}$ and followup ranged from 1 month to 6 years. Eleven of the studies measured compliance by pill count, coordinator "assessment," or self-
report. Mean baseline Tg ranged from 111 to $315 \mathrm{mg} / \mathrm{d}$ in 15 of the trials, was $682 \mathrm{mg} / \mathrm{d}$ in one study that included only people with severe hypertriglyceridemia ( $\geq 500 \mathrm{mg} / \mathrm{d}$ ) ${ }^{177}$ and was not reported in four trials. Excluding the trial of severe hypertriglyceridemia, net change Tg with EPA + DHA ranged from -109 (difference between final values) to $15 \mathrm{mg} / \mathrm{dL}$. The study of people with hypertriglyceridemia found large, significant net reductions of Tg with EPA+DHA doses of $1.5,2.25$, and $3 \mathrm{~g} / \mathrm{d}$ of $-156 \mathrm{mg} / \mathrm{d}$ (lower two doses) and $-173 \mathrm{mg} / \mathrm{d}(3 \mathrm{~g} / \mathrm{d})$. The pooled effect size (with the hypertriglyceridemia study) was a significant $-45.1 \mathrm{mg} / \mathrm{dL}(95 \%$ CI -61.2 to -29.0) (Figure 39); without Kastelein, the pooled net difference was identical.

## CVD Population

Ten trials compared EPA+DHA to placebo in 29,018 people with CVD. ${ }^{51,56,62,67,70,90,96, ~}$ ${ }^{119,121,125}$ EPA+DHA dosages ranged from 0.4 to $6 \mathrm{~g} / \mathrm{d}$ and followup ranged from 9 months to 4.6 y. All but one study measured, but few reported, compliance. Mean baseline Tg ranged from 137 to $191 \mathrm{mg} / \mathrm{d}$ when reported. Across trials, net change Tg with EPA+DHA ranged from -50 to $-3 \mathrm{mg} / \mathrm{dL}$. The pooled effect size was a significant $-20.1 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-33.5$ to -6.7 ) (Figure 39).

## RCT Subgroup Analyses

The four studies that examined subgroup effects of EPA+DHA on Tg based on statin use all found no significant interaction between marine oil and statins (Carrepeiro 2011, Holman 2009, Liu 2003, Vecka 2012). ${ }^{46,99,128,156}$ In one study each, no significant differences in effect were seen in those on high or low linoleic acid diets (Damsgaard 2008), ${ }^{94}$ in those receiving or not general diet counseling (Einvik 2010), ${ }^{115}$ or in older or younger age groups (Caslake 2008). ${ }^{97}$ One study found a significantly larger effect in people also taking a multivitamin ( $-76 \mathrm{mg} / \mathrm{dL}$ ) than in those without the multivitamin ( $-28 \mathrm{mg} / \mathrm{dL}$; P interaction $<0.05$ ), but Tg increased in only the group taking multivitamins and placebo (Earnest 2012). ${ }^{150}$ In contrast, one found a net increase in Tg concentration in people also taking vitamin C $(15 \mathrm{mg} / \mathrm{dL}$, due to a smaller decrease in Tg concentration than in the vitamin C alone group) and a large net decrease in people not taking vitamin $\mathrm{C}(-109 \mathrm{mg} / \mathrm{dL})$, but this difference in effect was not reported to be significantly different. ${ }^{76}$ One study examined gender effect and found that men on higher dose EPA+DHA ( $1.8 \mathrm{~g} / \mathrm{d}$ ) had a larger effect than women ( $\mathrm{P}<0.038$; difference not reported), but similar effects at lower dose ( $0.7 \mathrm{~g} / \mathrm{d}$ ) (Caslake 2008) ${ }^{97}$ One study found no difference in effect of EPA between people with either impaired glucose tolerance or noninsulin dependent diabetes or normoglycemia (Sirtori 1997), but among those with diabetes, those with lower HDL-c ( $\leq 35$ $\mathrm{mg} / \mathrm{dL}$ ) had a greater effect of EPA + DHA on $\operatorname{Tg}(-23.3 \%)$ than those with higher HDL-c ( $-16.9 \%$; P interaction $<0.05$ ). ${ }^{58}$ This difference in effect by HDL-c levels, however, was not seen among those with normoglycemia. One study of people with diabetes (Brinton 2013) found that with higher dose EPA+DHA ( $4 \mathrm{~g} / \mathrm{d}$ ) there was no difference in change in Tg by hemoglobin A1c level, but at $2 \mathrm{~g} / \mathrm{d}$, those with higher A1c levels (>6.8\%) had a smaller effect that was nonsignificant ( $-5 \%$ net change) compared to those with lower A1c levels ( $-15 \%, \mathrm{P}<0.01$ ), although the study did not analyze whether the interaction was significant. ${ }^{195}$

By meta-regression, across studies there were no significant differences in effect (interactions) by population (at risk $\mathrm{P}=0.30$; CVD $\mathrm{P}=0.52$ ) or followup duration ( $\mathrm{P}=0.49$ ). However, both mean baseline Tg level and EPA+DHA dose across studies were significantly associated with net change Tg. The primary metaregression was conducted excluding an outlier study (Kastelein 2014) of people with severe hypertriglyceridemia ( $\mathrm{Tg}>500 \mathrm{mg} / \mathrm{dL}$ at baseline),
who were found to have large net changes with EPA+DHA 3, 2.25, and $1.5 \mathrm{~g} / \mathrm{d} .{ }^{177}$ Analyses with this study, however, yielded similar results. Controlling for both variables, each increase in mean baseline Tg level by $1 \mathrm{mg} / \mathrm{dL}$ was associated with a greater net change Tg of $-0.15 \mathrm{mg} / \mathrm{dL}(95 \%$ CI -0.22 to $-0.08 ; \mathrm{P}<0.0001$ ) (Figure 40). Each increase of EPA+DHA dose by $1 \mathrm{~g} / \mathrm{d}$ was also associated with a greater net change Tg of $-5.9 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-9.9$ to -2.0 ; $\mathrm{P}=0.003$ ) (Figure 41). By spline analysis of the meta-regression, there was no clear inflection point where the association between dose and net change Tg substantially changed.

## Marine Oil, Comparison of Different Doses

Six RCTs directly compared different doses of marine oils (EPA+DHA), ${ }^{75,97,169,177,194,}$
${ }^{195}$ between 0.7 and $4 \mathrm{~g} / \mathrm{d}$. The trials compared EPA+DHA doses between 0.7 and $4 \mathrm{~g} / \mathrm{d}$. Only one of the six trials found a significant difference between higher ( $3.4 \mathrm{~g} / \mathrm{d}$ ) and lower ( $1.7 \mathrm{~g} / \mathrm{d}$ ) EPA + DHA (ethyl esters). ${ }^{169}$ Although, most trials found no significant difference, the differences in effect on Tg between doses ranged from -39 to $6 \mathrm{mg} / \mathrm{dL}$. A possible pattern could be discerned such that higher doses of 3.4 or $4 \mathrm{~g} / \mathrm{d}$ reduced Tg by at least $30 \mathrm{mg} / \mathrm{dL}$ more than lower doses of 1 to 2 g/d (Brinton 2013: 4 vs. 2 g/d; Oh 2014: 4 vs 2 g/d and 2 vs. 1 g/d; Tatsuno 2013: 3.4 vs. $1.7 \mathrm{~g} / \mathrm{d})$. Higher doses $\leq 3 \mathrm{~g} / \mathrm{d}(1.7-3 \mathrm{~g} / \mathrm{d})$ yielded much smaller relative differences in Tg change compared to lower doses $(0.7-2.25 \mathrm{~g} / \mathrm{d})(-17$ to $6 \mathrm{mg} / \mathrm{dL})$ (Caslake 2008: 1.8 vs. 0.7 g/d; Finnegan 2003: 1.7 vs. $0.8 \mathrm{~g} / \mathrm{d}$; Kastelein 2014: 3 vs. $2.25 \mathrm{~g} / \mathrm{d}$, 3 vs. $1.5 \mathrm{~g} / \mathrm{d}$, and 2.25 vs. $1.5 \mathrm{~g} / \mathrm{d}$; Oh 2014: 2 vs. $1 \mathrm{~g} / \mathrm{d}$ ).

## ALA Versus Placebo

Five trials compared ALA supplementation versus placebo (or equivalent), following 4940 patients for 1 to 40 months; one in healthy people, ${ }^{75}$ three in people at increased risk for CVD, ${ }^{152,167,180}$ and one in people with CVD. ${ }^{119}$ Doses of ALA ranged from 1.4 to $5.9 \mathrm{~g} / \mathrm{d}$, and baseline Tg measurements ranged from 144 to $150 \mathrm{mg} / \mathrm{dL}$. Compliance was measured in all studies, but not reported. All trials found no significant effect of total n-3 FA supplementation on Tg ; the estimates of the net differences ranged from -22 to 22 , mostly with wide confidence intervals.

## SDA Versus Placebo

Pieters 2015 compared $1.2 \mathrm{~g} / \mathrm{d}$ SDA to placebo in 32 patients at risk for CVD. At 1.5 month followup, no significant differences in change in Tg were found. ${ }^{188}$

## SDA Versus Marine Oil

Kuhnt 2014 compared $2.0 \mathrm{~g} / \mathrm{d}$ SDA and $1.9 \mathrm{~g} / \mathrm{d}$ EPA+DHA+DPA in 59 healthy people (broken into cohorts based on body mass index and age). At 2 month followup, no significant differences in change in Tg were found. ${ }^{178}$

## Comparison of Different Specific n-3 FA

Two trials directly compared EPA ( 3.8 or $3.3 \mathrm{~g} / \mathrm{d}$ ) to DHA ( 3.6 or $3.7 \mathrm{~g} / \mathrm{d}$ ), one of which evaluated EPA and DHA ethyl esters, ${ }^{61}$ one of which evaluated EPA- and DHA-enriched oils. ${ }^{107}$ Neither found a significant difference in effect on Tg between EPA and DHA. One trial compared two doses of EPA+DHA ( 3.4 and $1.7 \mathrm{~g} / \mathrm{d}$ ) to EPA $1.8 \mathrm{~g} / \mathrm{d}$ (all ethyl esters), ${ }^{169}$ finding significantly larger net reductions in Tg with either dose of EPA+DHA than EPA alone. Two trials compared EPA+DHA to ALA, one comparing two doses of EPA+DHA (1.7 and $0.8 \mathrm{~g} / \mathrm{d}$ ) to

ALA $4.5 \mathrm{~g} / \mathrm{d},{ }^{75}$ one comparing $0.4 \mathrm{~g} / \mathrm{d}$ EPA+DHA to $2 \mathrm{~g} / \mathrm{d}$ ALA. ${ }^{119}$ A possible dose effect of EPA + DHA was found in that the comparison with the highest dose of EPA + DHA ( $1.7 \mathrm{~g} / \mathrm{d}$ ) found a significantly greater effect of EPA+DHA than ALA ( $-28 \mathrm{mg} / \mathrm{dL} ; 95 \%$ CI -49 to -7 ) (Finnegan 2003), while in the same study a lower dose ( $0.8 \mathrm{~g} / \mathrm{d}$ ) had a smaller nonsignificant difference $(-14 \mathrm{mg} / \mathrm{dL})$, and the other study (Kromhout 2010), with EPA+DHA $0.4 \mathrm{~g} / \mathrm{d}$ had no differential effect ( $2.7 \mathrm{mg} / \mathrm{dL}$ ).

## Observational Studies

Observational studies did not evaluate Tg.

Abbreviations: ALA = alphalinolenic acid, Ctrl = control, CVD = cardiovascular disease, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, E:D = EPA to DHA ratio, EPA = eicosapentaenoic acid, F/up = followup, FA = fatty acid(s), FFQ = food frequency questionnaire, Int = intervention, $\mathrm{n} / \mathrm{N}=$ number with outcome/number analyzed, n6:3 = omega-6 to omega-3 fatty acid ratio, n-3 FA = omega-3 fatty acids, $\mathrm{ND}=$ no data, $\mathrm{NS}=$ not significant, $\mathrm{PMID}=$ PubMed Identification number, RCT = randomized controlled trial, SDA $=$ stearidonic acid.

Figure 39. Triglycerides: Randomized trials of marine oils

Random effects model meta-analysis of n-3 FA versus placebo (or no n-3 FA), with subgroup analyses by population. In all meta-analyses, only studies that reported sufficient results data are included.

Abbreviations: $\mathrm{CI}=$ confidence interval, $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DHA}=$ docosahexaenoic acid

Figure 40. Metaregression of effect of EPA+DHA on net change Tg, by mean baseline Tg

Association of mean baseline Tg (tgbaseline) in $\mathrm{mg} / \mathrm{dL}$ on net change Tg (tgnetdiff) in $\mathrm{mg} / \mathrm{dL}$.
Abbreviations: DHA = docosahexaenoic acid, EPA = eicosapentaenoic acid, $\mathrm{n}-3=$ omega- 3 fatty acids, $\mathrm{Tg}=$ triglycerides.

Figure 41. Metaregression of effect of EPA+DHA on net change Tg, by EPA+DHA dose

Association of EPA+DHA dose (nd_dose) in g/d on net change Tg (tgnetdiff) in mg/dL.
Abbreviations: DHA = docosahexaenoic acid, EPA = eicosapentaenoic acid, $\mathrm{Tg}=$ triglycerides.

## Total Cholesterol to HDL-c Ratio

## Randomized Controlled Trials

Eleven RCTs provided data on effect of n-3 FA on the ratio of total cholesterol to HDL-c (Total:HDL-c) (Table 44), ${ }^{61,115,116,119,136,166,167,169,177,180,188}$ one in a healthy population, eight in people at increased risk for CVD, and one in patients with CVD. Two of the trial reported Total:HDL-c among their primary outcomes (Grimsgaard 1998, Rodriguez-Leyva 2013). ${ }^{61,167}$

## Total n-3 FA Versus Placebo

Two trials compared total n-3 FA (ALA+EPA+DHA) versus placebo, following 2708 patients for 1 and 40 months; one in people at increased risk for CVD, ${ }^{180}$ one in people with CVD. ${ }^{119}$ Doses of ALA+EPA+DHA included ALA $1.2 \mathrm{~g} / \mathrm{d}$ and EPA+DHA+DPA $5 \mathrm{~g} / \mathrm{d}$, and ALA $2 \mathrm{~g} / \mathrm{d}$ and EPA+DHA $0.4 \mathrm{~g} / \mathrm{d}$. Baseline Total:HDL-c ratio was 4.0 in one trial and not reported in the other. Compliance was measured in both studies, but not reported. The estimates of the net differences were not significant, one with a wide confidence interval.

## Marine Oil Versus Placebo

Eight trials compared marine oil supplementation to placebo. $61,115,116,119,136,166,177,180$ Six of eight trials found statistically significant reductions in Total:HDL-c ratios. Across populations, by meta-analysis, the summary net difference in Total:HDL-c ratio with EPA+DHA versus placebo was a statistically significant -0.17 ( $95 \%$ CI -0.26 to -0.09 ) (Figure 42). Across studies, by metaregression, effect sizes did not statistically differ by population (at risk $\mathrm{P}=0.57$, CVD $\mathrm{P}=0.61$ ), marine oil dose ( $\mathrm{P}=0.67$ ), or baseline ratio ( $\mathrm{P}=0.16$ ).

## Healthy Population

Two trials compared both EPA, DHA, and EPA+DHA separately to a placebo in 536 healthy participants, total. ${ }^{61,136}$ Compliance was assessed with pill count and plasma checks. The baseline Total:HDL-c ratio in the placebo group ranged from 3.53 to 4.43 and followup ranged from 2 months to 1 year. The Grimsgaard trial found significant reductions with both ethyl ester marine oils compared to placebo ( -0.2 and -0.3 ). While the Sanders trial found nonsignificant net change results between interventions and placebo. The two trials yielded a subgroup metaanalysis summary effect of $-0.16(95 \% \mathrm{CI}-0.32$ to -0.01$)$.

## At-Risk-for-CVD Population

Six trials compared EPA+DHA to placebo in 1185 people at increased risk for CVD. ${ }^{115}$, 116, 119, 166, 177, 180 Compliance was assessed by pill count or meal consumption in two trials. EPA+DHA dosages ranged from 1.5 to $5 \mathrm{~g} / \mathrm{d}$ and followup ranged from 1 month to 3 years. Baseline Total:HDL-c ratios ranged from 4.29 to 4.7 in four trials and was 8.8 in one trial of patients (Kastelein 2014) with severe hypertriglyceridemia ( $\geq 500 \mathrm{mg} / \mathrm{dL}$ ) at baseline. ${ }^{177}$ All but one trial found a significant reduction in Total:HDL-c ratio. Net change Total:HDL-c ratio varied between -1.2 and -0.1 . The pooled effect size was a statistically nonsignificant -0.24 (95\% CI -0.35 to -0.14 ). Exclusion of Kastelein 2014 did not substantially affect the pooled estimate.

## CVD Population

One trial compared 3 months of $0.4 \mathrm{~g} / \mathrm{d}$ EPA+DHA in patients with CVD and found a net change of $-0.03(95 \% \mathrm{CI}-0.17$ to 0.10$) .{ }^{119}$ Separate analyses were reported for patient taking
statins or not. The study did not report compliance information. Baseline Total:HDL-c ratio data were also not reported. In both subgroups, no significant change in Total:HDL-c ratio was found, but there was a net increase in the ratio (0.09) in patients not taking statins and a net decrease in the ratio $(-0.07)$ in those on statins.

## RCT Subgroup Analyses

In the trial of patients with CVD, there was no apparent difference in effect on
Total:HDL-c ratio based on cointervention with statins. ${ }^{119}$ In a trial of people at increased risk of CVD, there was no interaction between EPA+DHA and general diet counseling.

By meta-regression, across studies there were no significant differences in effect (interactions) followup duration ( $\mathrm{P}=0.17$ ). However, the at risk for CVD population, mean baseline Total:HDL-c ratio level and EPA+DHA dose across studies were significantly associated with net change Total:HDL-c ratio. Controlling for these three variables, each increase in mean baseline Total:HDL-c level by 1 was associated with a greater net change Total:HDL-c of -0.16 ( $95 \% \mathrm{CI}-0.25$ to -0.07 ; $\mathrm{P}=0.0008$ ). Each increase of EPA+DHA dose by $1 \mathrm{~g} / \mathrm{d}$ was also associated with a greater net change Total:HDL-c of -0.07 ( $95 \% \mathrm{CI}-0.11$ to $-0.02 ; \mathrm{P}=0.003$ ). The at risk for CVD population was associated with a greater net change Total:HDL-c of 0.77 ( $95 \%$ CI 0.29 to 1.25 ; $\mathrm{P}=0.002$ ).

## Marine Oil, Comparison of Different Doses

As noted, the trial of people with severe hypertriglyceridemia compared three doses of EPA+DHA (3, 2.25, and $1.5 \mathrm{~g} / \mathrm{d}$ ). ${ }^{177}$ At 3 month followup, the net differences among the three doses were not significantly different from each other. A second trial, comparing 2 and $4 \mathrm{~g} / \mathrm{d}$ of total oil (of EPA+DHA) also found no significant differences in effect between the two doses at 1.5 months. ${ }^{166}$ A third trial, comparing $3.36 \mathrm{~g} / \mathrm{d} 1.68 \mathrm{~g} / \mathrm{d}$ of EPA+DHA also found no significant differences in effect between the two doses at 1 year.

## ALA Versus Placebo

Three trials evaluated ALA versus placebo. ${ }^{119,167,180}$ In a trial of people at increased risk for CVD, no significant effects of ALA (both 1.4 and $5.9 \mathrm{~g} / \mathrm{d}$ ) were found on Total:HDL-c ratios at 1 month in 390 participants. ${ }^{180}$ No difference in effect between the two doses was found in this trial. Similarly no significant effects were found in a trial of $2 \mathrm{~g} / \mathrm{d}$ ALA in 2,088 people with CVD at 3.4 years. ${ }^{119}$ or in a trial of $5.9 \mathrm{~g} / \mathrm{d}$ ALA in 48 people at 1 year. ${ }^{167}$

## Comparison of Different Specific n-3 FA

Grimsgaard 1998 compared EPA $3.8 \mathrm{~g} / \mathrm{d}$ and DHA $3.6 \mathrm{~g} / \mathrm{d}$ ethyl esters in 157 healthy people for 2 months. No difference in net change Total:HDL-c ratio was found. ${ }^{61}$ Tatsuno 2013 compared two doses of EPA+DHA ( 3.36 and $1.68 \mathrm{~g} / \mathrm{d}$ ) to EPA $1.8 \mathrm{~g} / \mathrm{d}$ alone (all ethyl esters). ${ }^{169}$ Again, no differences in effect on Total:HDL-c ratio were found. Jones 2014 compared $5.9 \mathrm{~g} / \mathrm{d}$ and $1.4 \mathrm{~g} / \mathrm{d}$ of ALA. Again, no difference in effect on Total:HDL-c ratio were found. ${ }^{180}$

## SDA Versus Placebo

Pieters 2015 compared 1.2 g/d SDA to placebo in 32 patients at risk for CVD. At 1.5 month followup, no significant differences in change Total:HDL-c ratio were found. ${ }^{188}$

## Observational Studies

Observational studies did not evaluate Total:HDL-c ratio.

Random effects model meta-analysis of n-3 FA versus placebo (or no n-3 FA), with subgroup analyses by population. In all meta-analyses, only studies that reported sufficient results data are included.

Abbreviations: $\mathrm{CI}=$ confidence interval, $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DHA}=$ docosahexaenoic acid, DPA $=$ docosapentaenoic acid, $\mathrm{EPA}=$ eicosapentaenoic acid, HDL-c = high density lipoprotein cholesterol, n-3 FA = omega-3 fatty acid, Phet = P value of chi-squared test of heterogeneity across studies, PMID = PubMed Identification number.

## LDL-c to HDL-c Ratio

## Randomized Controlled Trials

Five RCTs provided data on effect of n-3 FA on the ratio of LDL-c to HDL-c (LDL:HDL-c) (Table 45), ${ }^{46,76,167,169,178}$ one studied a healthy population, while four looked at people at increased risk for CVD. Two of the trials reported LDL:HDL-c among their primary outcomes (Rodriguez-Leyva 2013, Shidfar 2003). ${ }^{76,167}$

## Marine Oil Versus Placebo

Liu 2003 compared $2.8 \mathrm{~g} / \mathrm{d}$ of EPA+DHA to placebo in 88 people at increased risk for CVD. ${ }^{46}$ Baseline LDL:HDL-c ratio was about 3.1. Analyses were reported separately for a factorial analysis with simvastatin. At 3 month followup, no effect of LDL:HDL-c ratio was found with EPA+DHA supplementation in either subgroup, with no difference in effect regardless of simvastatin cotreatment.

Shidfar 2003 compared $0.81 \mathrm{~g} / \mathrm{d}$ of EPA+DHA to placebo in 68 people at increased risk for CVD. ${ }^{76}$ Baseline LDL:HDL-c ratio was about 4.2. Analyses were reported separately for a factorial analysis with vitamin C. At 2.5 month followup, no effect of LDL:HDL-c ratio was found with total n-3 FA supplementation in either subgroup, with no difference in effect regardless of vitamin C cosupplementation.

Tatsuno 2013 (in a trial without a placebo arm) compared 3.36 and $1.68 \mathrm{~g} / \mathrm{d}$ EPA+DHA ethyl esters in 335 people at increased risk for CVD. ${ }^{169}$ At 3 month followup, no significant difference in change in LDL:HDL-c ratio was found.

## ALA Versus Placebo

One trial evaluated ALA versus placebo. ${ }^{167}$ In 84 people at increased risk for CVD, no significant effects of ALA ( $5.9 \mathrm{~g} / \mathrm{d}$ ) were found on LDL:HDL-c ratios at 1 year.

## Comparison of Different Specific n-3 FA

Tatsuno 2013 compared 3.36 and $1.68 \mathrm{~g} / \mathrm{d}$ EPA+DHA and $1.8 \mathrm{~g} / \mathrm{d}$ EPA (all ethyl esters) in 502 people at increased risk for CVD. ${ }^{169}$ At 3 month followup, no significant differences in change in LDL:HDL-c ratios were found.

## SDA Versus Marine Oil

Kuhnt 2014 compared $2.0 \mathrm{~g} / \mathrm{d}$ SDA and $1.9 \mathrm{~g} / \mathrm{d}$ EPA+DHA+DPA in 59 healthy people (broken into cohorts based on body mass index and age). At 2 month followup, no significant differences in change in LDL:HDL-c ratios were found. ${ }^{178}$

## Observational Studies

Observational studies did not evaluate Total:HDL-c ratio.

## Adverse Events

Of 61 RCTs included in this systematic review, only 4 RCTs of EPA/DHA ethyl ester, 19 RCTs of marine oils (EPA+DHA), 1 RCT of ALA, and 1 RCT comparing total n-3 FA, marine oil, ALA, and placebo reported information on adverse events that may or may not be associated with the interventions (Table 46). ${ }^{53,58,61,62,70,81,87,90,96,99,115,116,119,123,133,147,151,157, ~ 166, ~ 167, ~ 169, ~}$ 174, 177, 184, 187 There were no serious adverse events that were considered related to the study interventions in these 25 RCTs. Four of the 20 marine oil RCTs and one of the two ALA trials reported no adverse events. Most of the reported adverse events were mild and transient, such as gastrointestinal discomforts, nausea, skin abnormalities, eczema, pain, allergic reactions, fishy taste, headache, and infection. The most common adverse events related to n-3 FA supplements (that occurred more frequently among those taking supplements) were mild gastrointestinal effects such as belching ( $0.4-58 \%$ [marine oil] vs. 1.7-4\% [placebo]; 2 studies), nausea (3.6-8.9\% vs. $1.0-5.6 \%$, 2 studies), diarrhea ( $5.1-8.9 \%$ vs. $2.0 \%$, 1 study), or fishy taste ( $5.3-67 \%$ vs. $0-3 \%$, 2 studies), or combined gastrointestinal symptoms (e.g., nausea, diarrhea, or epigastric discomfort) (marine oil: $1.5 .0-6 \%$ vs. 0.8-4.5\%, 7 studies; total n-3 FA: $1.3 \%$ vs. $0.8 \%$, 1 study; ALA: $0.8 \%$ vs. $0.8 \%$ ). Only one study explicitly reported on bleeding (hemorrhages such as cerebral and fundal bleedings, epistaxis, and subcutaneous bleeding), finding a higher rate with EPA ethyl ester and statin (1.1\%) versus statin alone ( $0.6 \%, \mathrm{P}<0.0001$ ) (Yokoyama 2007). This study was one of only two trials that reported statistically significantly more adverse events with marine oils than placebo (Yokoyama 2007, Kastelein 2014 [total adverse events only]; see Table 42). No study reported statistically significant higher rates of serious or severe adverse events between study arms, and no serious or severe adverse event was attributed to n-3 FA. Six of the marine oil trials explicit stated that most or all adverse events were mild (Einvik 2010, Grimsgaard 1998, Ras 2014, Shaikh 2014, Tatsuno 2013, Yokoyama 2007). Three studies reported on the rate of adverse events leading to discontinuation, none of which were reported as statistically significantly different between groups (1.4-17\% vs. 0.9-26\%).

Abbreviations: $\mathrm{Abnl}=$ abnormal, $\mathrm{AE}=$ adverse event, $\mathrm{ALA}=$ alphalinolenic acid, $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DHA}=$ docosahexaenoic acid, $\mathrm{EPA}=$ eicosapentaenoic acid, $\mathrm{F} /$ up $=$ followup, $\mathrm{GI}=$ gastrointestinal, n-3 FA = omega-3 fatty acids, NS = not significant, PMID = PubMed Identification number.

## Summary by n-3 FA

The trials of clinical outcomes were almost all conducted in populations at increased risk of CVD, largely related to dyslipidemia, or with CVD. The trials that reported intermediate outcomes (BP and lipoproteins), were conducted in generally healthy, at-risk, and CVD populations. The observational studies, in contrast, were almost all conducted in general (unrestricted by CVD or risk factors) or healthy populations. One observational study evaluated BP; none evaluated lipids.

## Total n-3 FA (ALA+EPA+DHA)

Overall, there is insufficient evidence regarding the effect of or association between total n-3 FA (combined ALA and marine oils) and clinical or intermediate outcomes (Table 47). There is low strength of evidence of no association between total n-3 FA intake and stroke death, and total (fatal and nonfatal) MI (each association based on longitudinal observational studies of dietary intake). For both outcomes, the strength of evidence was rated low because of a lack of confirmatory RCT data.

## Clinical Event Outcomes, RCTs

No RCTs reported clinical event outcomes for comparisons of total n-3 FA versus placebo.

## Intermediate Outcomes, RCTs

Two RCTs that evaluated BP compared combined ALA and marine oil (ALA $1.2 \mathrm{~g} / \mathrm{d}$ [canola oil] or 2 g ["plant oil"], and 3.6 or 0.4 g EPA+DHA) versus placebo reported on intermediate outcomes. Neither trial found significant effects on BP, LDL-c, HDL-c, Tg, or Total:HDL-c ratio.

## Observational Studies, Intake

Seven studies evaluated total n-3 FA intake. For each outcome there was no consistent (and replicated) significant association between total n-3 FA intake and risk reduction. One of three studies found a significant association between higher total n-3 FA intake and higher risk of MACE. In contrast, one of three studies found an association with reduced risk of CVD death; one of two studies found a significant association with MI death; one study each found significant associations with lower risk of ischemic stroke death and CHF death. No studies found significant associations with all-cause death (1 study), CHD death (2 studies), total (ischemic and hemorrhagic) stroke death (3 studies), MI (1 study), total (fatal and nonfatal) stroke (1 study), SCD (1 study), or incident hypertension (1 study).

One study found no significant difference in association of total n-3 FA with total CVD death between men and women or by amount of fish consumption. Another study found no significant difference in association with MI death, total stroke death, or ischemic stroke death by baseline Total:HDL-c ratio.

## Observational Studies, Biomarkers

Three studies evaluated biomarkers for total n-3 FA (combined; plasma, blood, or erythrocyte). One study evaluated numerous outcomes and found significant associations
between higher biomarker level and reduced risk of most outcomes (CVD death, CHD death, allcause death, CHD, ischemic stroke, SCD, AFib, and CHF), but not stroke death, total stroke, or hemorrhagic stroke. In contrast, a second study found no significant association with CHD. The third study found no significant association overall with incident hypertension, but did find a significant association in between higher total n-3 FA and hypertension in younger women ( $<55$ years old) but not in older women.

Table 47. Evidence profile for the effect and association of total n-3 FA with CVD outcomes*

* No reporting bias was detected for any outcome. All studies that measured n-3 FA intake were assessed to be direct, while all biomarker studies were assessed to be indirect.

Abbreviations: $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DBP}=$ diastolic blood pressure, HDL-c = high density lipoprotein cholesterol, LDL-c = low density lipoprotein cholesterol, MACE $=$ major adverse cardiovascular event (including cardiac and stroke events and death; variously defined by studies), MAP = mean arterial blood pressure, $n-3 F A=0 m e g a-3$ fatty acids, $N A=$ not applicable, Obs $=$ observational study, RCT = randomized controlled trial, SBP = systolic blood pressure, SoE = strength of evidence.

## Marine Oil, Total: EPA+DHA $\pm$ DPA

Overall, there is low, moderate, or high strength of evidence of no effect (or association) of marine oils and most clinical CVD outcomes and BP, and high strength of evidence of significant effects of higher marine oil intake on lipoproteins and Tg. (Table 48). There is insufficient evidence for many outcomes of interest. Specifically, there is high strength of evidence of that marine oils statistically significantly lower Tg-possibly with greater effects with higher doses and in people with higher baseline Tg —and statistically significantly raise HDL-c and LDL-c by similar amounts. There is also high strength of evidence that marine oil significantly lowers Total:HDL-c ratio and low strength of evidence that marine oil significantly lowers risk of ischemic stroke (for which no RCTs confirmed the observational study finding). There is a high strength of evidence of no effect of marine oil on risk of MACE, all-cause death, SCD, revascularization, and BP, moderate strength of evidence of no effect of marine oil on risk of AFib, and low strength of evidence of no effect of marine oil on risk of CVD death, CHD death, total CHD, MI, CHF, total stroke, and hemorrhagic stroke. Strength of evidence was rated as low for CHD and hemorrhagic stroke due to a lack of confirmatory RCT data; and for CVD death, CHF, and total stroke because RCTs and observational studies yielded conflicting conclusions (RCTs found no effect, observational studies found statistically significant associations). Strength of evidence was rated low for CHD death primarily because RCTs and observational studies both yielded imprecise estimates suggesting no effect/association. For MI, the strength of evidence was rated low primarily because the summary effect size estimate was relatively strong ( $\mathrm{HR}=0.88$ ), but the $95 \% \mathrm{CI}$ only minimally crossed the significance threshold ( $95 \%$ CI 0.77 to 1.02 ); this scenario yielded low confidence that the conclusion would remain stable with future RCTs and subsequent greater statistical power. This issue was also pertinent for CVD death where summary HR $=0.92$ ( $95 \%$ CI 0.82 to 1.02). There is insufficient evidence for other outcomes.

Four RCTs explicitly evaluated (purified) EPA and/or DHA ethyl esters; ${ }^{61,90,96,161,169}$ all other trials explicitly or implicitly evaluated marine oil preparations. No study directly compared formulations. The effects on clinical and intermediate outcomes found among the ethyl ester trials were all statistically or qualitatively similar to the effects found in other studies.

## Clinical Event Outcomes, RCTs

Regarding clinical event outcomes, 19 trials in populations at increased risk for CVD (3 RCTs) and CVD populations ( 17 RCTs) mostly found no significant effects of marine oil (EPA+DHA $\pm$ DPA) versus placebo on specific clinical event outcomes. Across RCTs, EPA+DHA doses ranged from 0.34 to $6 \mathrm{~g} / \mathrm{d}$ (median $0.866 \mathrm{~g} / \mathrm{d}$ ). Followup ranged from 1 to over 10 years (median 3.9 years).

Two of 17 trials found significantly lower risk of all-cause death with EPA+DHA (both $0.866 \mathrm{~g} / \mathrm{d}$; HR = 0.79 and 0.91), however, the meta-analyzed HR was nonsignificant at 0.97 ( $95 \%$ CI 0.92 to 1.03 ) with no differences across trials by marine oil dose, followup time, or population (CVD, at risk, healthy). Four trials also found no within-study subgroup differences in effect on death for multiple subgroup comparisons.

Ten RCTs reported on MACE, only two of which found significant reductions in outcome with $0.866 \mathrm{~g} / \mathrm{d}$ EPA+DHA at 3.9 year followup and with $1.8 \mathrm{~g} / \mathrm{d}$ EPA at 5 year followup (in an at-risk population, but not in a parallel CVD population). Meta-analysis of MACE found a no effect (HR=0.96; 95\% CI 0.91 to 1.02) with no significant differences across
studies by marine oil dose (range $0.4-2 \mathrm{~g} / \mathrm{d}$ ), followup time (range $1-5 \mathrm{y}$ ), or population category. Within-study subgroup analyses found a significant effect in women but not men in one trial, but no significant difference in effect between sexes in a second trial, and no differences between multiple subgroups in three trials.

None of the 11 trials that reported on total MI found a significant effect. Meta-analysis, however, found a nonsignificant effect size ( $\mathrm{HR}=0.88$; $95 \%$ CI 0.77 to 1.02 ), with no significant differences across studies by marine oil dose, followup time, or population category. In one trial, no significant difference in effect was found based on cointervention with B vitamins.

Two of seven RCTs found significant effects of $0.866 \mathrm{~g} / \mathrm{d}$ marine oil (EPA+DHA) on risk of CVD death in populations of people with existing CVD. Meta-analysis found a nonsignificant effect size (HR=0.92; 95\% CI 0.82 to 1.02), with no significant differences across studies by marine oil dose, followup time, or population.

Nine RCTs all found no significant effect of EPA+DHA with SCD; by meta-analysis (with the EPA trial), summary HR=1.04 (95\% CI 0.92 to 1.17). Seven RCTs also found no significant effect of marine oils with total stroke; by meta-analysis, summary HR=0.98 (95\% CI 0.88 to 1.09).

Six RCTs evaluated angina pectoris, three stable angina, one hospitalization for angina, and three unstable angina. One trial found that $1.8 \mathrm{~g} / \mathrm{d}$ of purified EPA ethyl ester had an additive effect on statin to reduce unstable angina incidence after 5 years in people with dyslipidemia; however the five trials in people with existing CVD found no significant effects of 0.84 to $6 \mathrm{~g} / \mathrm{d}$ marine oils. The six RCTs evaluating CHF had a similar pattern. The one trial of $0.85 \mathrm{~g} / \mathrm{d}$ marine oil in people with multiple risk factors for CHF found a significant risk reduction in CHF hospitalization with n-3 FA supplementation, but the five studies in people with existing CVD found no significant effects of 0.84 to $6 \mathrm{~g} / \mathrm{d}$ marine oils.

All EPA+DHA RCTs that evaluated revascularization (6 trials), CHD death (4 trials), total stroke death (3 trials), AFib (3 trials), and CHF death (1 trial) found no significant effect of marine oils. One trial found an effect in participants with diabetes that was not seen in those without diabetes, but no test of interaction was reported. Two trials compared effect of marine oils on AFib in multiple subgroups, finding no significant differences.

Four EPA+DHA RCTs found inconsistent effects on cardiac death, with effect sizes ranging from 0.45 to 1.45 . One trial found a statistically significant reduction in cardiac death with $0.866 \mathrm{~g} / \mathrm{d}$ EPA+DHA at 3.5 years ( $\mathrm{RR}=0.65$; 95\% CI 0.51 to 0.82 ); one trial found a statistically significant increase in cardiac death with a fish diet with EPA+DHA supplements ( 0.855 g/d EPA+DHA; HR=1.45; 95\% CI 1.05 to 1.99), but no significant effect on cardiac death among people only given advice to increase fish intake (by $0.45 \mathrm{~g} / \mathrm{d}$ EPA+DHA) or in two other trials of 0.96 and $2.6 \mathrm{~g} / \mathrm{d}$ EPA+DHA. The trial that found increased risk with combined fish diet and EPA+DHA supplementation found no significant difference in effect between multiple sets of subgroups based on drug cointervention.

## Intermediate Outcomes, RCTs

Twenty-nine RCTs that compared EPA+DHA to placebo evaluated systolic BP, of which 28 also reported on diastolic BP. Ten RCTs were in healthy populations, 13 in those at risk for CVD, and six in those with CVD. All trials found no significant difference in BP across EPA+DHA doses of 0.30 to $6 \mathrm{~g} / \mathrm{d}$ and followup durations of 1 month to 6 years. By metaanalysis, no significant effects on systolic (summary net difference $=0.10 \mathrm{mmHg} ; 95 \% \mathrm{CI}-0.20$ to 0.40 ) or diastolic (summary net difference $=-0.19 \mathrm{mmHg} ; 95 \% \mathrm{CI}-0.43$ to 0.05 ) BP were
found. Four of the trials also found no effect on MAP. By meta-regression, no differences in effect across studies were found by marine oil dose, followup duration or population. Three trials directly compared different EPA+DHA doses and found no differences in effect ( $1.7 \mathrm{vs} .0 .8 \mathrm{~g} / \mathrm{d}$; 1.8 vs. 0.9 or $0.45 \mathrm{~g} / \mathrm{d} ; 3.4 \mathrm{vs} .1 .7 \mathrm{~g} / \mathrm{d}$ ). One trial found no difference in effect between people with normal BP or prehypertension.

Numerous included RCTs compared the effect of marine oils and placebo (or equivalent) on blood lipids. Thirty-nine RCTs evaluated LDL-c and 34 evaluated HDL-c. Marine oil doses ranged from 0.3 to $6 \mathrm{~g} / \mathrm{d}$ (median $2.4 \mathrm{~g} / \mathrm{d}$ ) and study followup times ranged from 1 month to 6 years (median 3 months). Meta-analysis of the effect of marine oils on LDL-c found a statistically significant, but small effect increasing LDL-c ( $1.98 \mathrm{mg} / \mathrm{dL}$; 95\% CI 0.38 to 3.58 ). Marine oils increased HDL-c also by a statistically significant, but small effect ( $0.92 \mathrm{mg} / \mathrm{dL}$; 95\% CI 0.18 to 1.66). For both lipoprotein fractions, no significant differences in effect across studies were found by marine oil dose, followup duration or population. Seven studies found no significant differences in effect within study by EPA+DHA dose. For HDL-c, three trials found no significant difference in effect between people using statins or not; one or two trials, each, found no significant differences between subgroups based on sex or age. One trial found a larger HDL-c effect in a subgroup also randomized to an exercise regimen; one of two trials found a larger HDL-c effect in people with impaired glucose tolerance compared to those with normoglycemia. Eight trials mostly found no significant effects of marine oil ( $0.4-5 \mathrm{~g} / \mathrm{d}$ for 1 month to 3 years) on Total:HDL-c ratio, but with a statistically significant summary effect of -0.17 ( $95 \% \mathrm{CI}-0.26$ to -0.09 ). One trial of $2.8 \mathrm{~g} / \mathrm{d}$ EPA+DHA found no significant effect on LDL:HDL-c ratio; another trial found no significant difference in change in ratio between 3.4 and $1.7 \mathrm{~g} / \mathrm{d}$ EPA+DHA.

Forty-one included RCTs mostly found significant effects of marine oils ( $0.3-6 \mathrm{~g} / \mathrm{d}$; median $2.4 \mathrm{~g} / \mathrm{d}$ for 1 month to 6 years; median 3 months) on Tg levels. Meta-analysis found a summary net change of $-24 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-31$ to -18 ), with no significant difference in effect based on population or followup time across studies. By metaregression, each increase in mean baseline Tg concentration by $1 \mathrm{mg} / \mathrm{dL}$ was associated with a greater net decrease in Tg concentration of $-0.15 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.22$ to -0.08 ; $\mathrm{P}<0.0001$ ); each increase of EPA+DHA dose by $1 \mathrm{~g} / \mathrm{d}$ was also associated with a greater net decrease in Tg concentration of $-5.9 \mathrm{mg} / \mathrm{dL}$ ( $95 \%$ CI -9.9 to -2.0 ; $\mathrm{P}=0.003$ ). No clear inflection point was found at any dose. Five of six trials found no significant difference in Tg change by EPA+DHA dose, but across trials all doses of 3.4 and $4 \mathrm{~g} / \mathrm{d}$ lowered $T \mathrm{~g}$ concentration by at least $30 \mathrm{mg} / \mathrm{dL}$ more than lower doses ( $1-2 \mathrm{~g} / \mathrm{d}$ ), while all pairwise comparisons of lower doses ( $1.7-3 \mathrm{~g} / \mathrm{d}$ ) to even lower doses ( $0.7-2.25 \mathrm{~g} / \mathrm{d}$ ) found much smaller differences between doses ( -17 to $6 \mathrm{mg} / \mathrm{dL}$ ). Two trials both found significantly larger Tg concentration lowering effects of EPA ( 3.6 or $3.3 \mathrm{~g} / \mathrm{d}$ ) than DHA ( 3.8 or $3.7 \mathrm{~g} / \mathrm{d}$ ). No significant differences were found based on statin use ( 4 trials), vitamin C use (1 trial), concurrent high or low linoleic acid diet (1 trial), concurrent general dietary advice (1 trial), or age (1 trial). One trial found a significantly larger effect on Tg among people also taking a multivitamin. One trial found a larger effect of higher dose EPA+DHA ( $1.8 \mathrm{~g} / \mathrm{d}$ ) in men than women, but no significant difference between sexes at $0.8 \mathrm{~g} / \mathrm{d}$. One trial found no significant difference in effect between people with impaired glucose tolerance and those with noninsulin dependent diabetes, but among those with diabetes, a larger effect was found in those with baseline HDL-c $\leq 35 \mathrm{mg} / \mathrm{dL}$ compared to higher levels.

## Observational Studies, Intake

Twenty-one observational studies evaluated associations between total EPA + DHA $\pm$ DPA intake (regardless of source) and numerous clinical outcomes. Only eight (38\%) of these found significant associations with any clinical outcome.

By meta-analysis, overall there is a statistically significant association between marine oil intake and CVD death across a median dose range of 0.066 to $1.58 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=$ 0.88 ; $95 \%$ CI 0.82 to 0.95 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1). This implies the possibility of a ceiling effect (where intake above a certain level adds no further benefit). However, at no dose threshold was there a statistically significant difference between the ES below the dose threshold (knot) and above the threshold. The best fit curve was found with a knot at $0.3 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at $0.2 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.26)$.

By meta-analysis, overall there no significant association between marine oil intake and CHD death across a median dose range of 0.04 to $2.1 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=1.09$; $95 \%$ CI 0.76 to 1.57). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) found stronger associations (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1) for knots below $0.7 \mathrm{~g} / \mathrm{d}$, but stronger associations at higher doses above $0.7 \mathrm{~g} / \mathrm{d}$. However, the differences in effect size between lower and higher doses were always highly nonsignificant, implying no difference in association. The best fit curve was found with a knot at $0.5 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at the lowest tested threshold, 0.1 $\mathrm{g} / \mathrm{d}(\mathrm{P}=0.46)$.

By meta-analysis, overall there no significant association between marine oil intake and all-cause death across a median dose range of 0.066 to $1.58 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.62$; $95 \%$ CI 0.31 to 1.25 ). However, meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) consistently found stronger associations (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1 ). This implies the possibility of a ceiling effect (where intake above a certain level adds no further benefit). For thresholds $\leq 0.4 \mathrm{~g} / \mathrm{d}$ the associations are statistically significant at lower doses, but not statistically significant at higher doses. The difference between low- and high-dose associations is statistically significantly different at a threshold of $0.2 \mathrm{~g} / \mathrm{d}$ ( $\mathrm{P}=0.047$ ). The best fit curve was found with a knot at $0.3 \mathrm{~g} / \mathrm{d}$. This analysis may suggest that marine oil intake above about 0.2 to $0.4 \mathrm{~g} / \mathrm{d}$ may not further strengthen any association between higher marine oil intake and lower rate of all-cause death.

By meta-analysis, overall there no significant association between marine oil intake and CHD across a median dose range of 0.038 to $3.47 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.94$; 95\% CI 0.81 to 1.10]). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.4 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1, ES above know about 1). At all knot points the differences were nonsignificant. This weakly suggests the possibility of a ceiling effect (where intake above a certain level adds no further benefit). The best fit curve was found with a knot at $0.4 \mathrm{~g} / \mathrm{d}$. The P values for differences between lower- and higher-dose knots were between 0.12 and 0.14 at all knots $\geq 0.3 \mathrm{~g} / \mathrm{d}$.

By meta-analysis, overall there is a statistically significant association between marine oil intake and total stroke across a median dosage range of 0.025 to $0.6 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=$ 0.68 ; $95 \%$ CI 0.53 to 0.87 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found a much stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below know less than 1; ES above know greater than 1); although, the difference in effect sizes above and below the knots were never statistically significant This implies a possible ceiling effect ceiling effect (where intake above a certain level adds no further benefit). However, given that the differences between lower and higher dose ES remained large across the range of testable dose thresholds, the actual ceiling dose threshold may be above the analyzable range (i.e., $>0.5 \mathrm{~g} / \mathrm{d}$ ). The best fit curve was found with the lowest knot at $0.1 \mathrm{~g} / \mathrm{d}$. The P values for differences between lower- and higher-dose effect sizes ranged from 0.14 to 0.20 .

By meta-analysis, overall there is a statistically significant association between higher marine oil intake and lower risk of ischemic stroke across a median dosage range of 0.025 to 0.6 $\mathrm{g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.51$; $95 \%$ CI 0.29 to 0.89 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found a much stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot near or greater than 1). All effect sizes below the knots were statistically significant and all above the knots were nonsignificant. The differences between lower- and higher-dose effect sizes were all statistically significant ( $\mathrm{P}=0.03-0.049$ ). This implies a ceiling effect (where intake above a certain level adds no further benefit). However, it is unclear what the threshold may be, as it may be greater than the highest threshold tested ( 0.4 $\mathrm{g} / \mathrm{d}$ ). The best fit curve was found with a knot at either 0.3 or $0.4 \mathrm{~g} / \mathrm{d}$. The difference between lower-dose and higher-dose ES estimates was statistically significant with a knot at $0.1 \mathrm{~g} / \mathrm{d}$.

By meta-analysis, overall there is no significant association between marine oil intake and hemorrhagic stroke across a median dosage range of 0.025 to $0.6 \mathrm{~g} / \mathrm{d}$ (effect size per g/d = $0.61 ; 95 \%$ CI 0.34 to 1.11 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found similar associations above and below the knots. At no threshold was the difference in effect sizes statistically significant. The best fit curve was found with a knot at $0.1 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at $0.5 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.78)$.

By meta-analysis, overall there is a just-significant association between higher marine oil intake and decreased risk of CHF across a median dosage range of 0.014 to $0.71 \mathrm{~g} / \mathrm{d}$ (effect size per $g / d=0.76 ; 95 \%$ CI 0.58 to 1.00 ). Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk) at lower doses than at higher doses (ES below knot less than 1; ES above knot closer to 1). This implies the possibility of a ceiling effect (where intake above a certain level adds no further benefit). However, given that the differences between lower and higher dose ES remained large across the range of testable dose thresholds, the actual ceiling dose threshold may be above the analyzable range (i.e., $>0.5 \mathrm{~g} / \mathrm{d}$ ). At thresholds of 0.1 and $0.2 \mathrm{~g} / \mathrm{d}$, the difference in effect size at lower and higher doses were statistically significant ( P values 0.04 and 0.03 , respectively). But the most significant difference was found at the highest threshold tested, $0.5 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.02)$. The best fit curve was found with the lowest knot tested, 0.1 g/d.

A minority of studies found significant associations of decreased risk of other outcomes with increasing intake of $\mathrm{EPA}+\mathrm{DHA} \pm$ DPA: MACE (1 of 2 studies), all-cause death (1 of 3
studies), CVD death (1 of 4 studies), CHD death (3 of 7 studies), MI (1 of 2 studies), incident CHF (1 of 5 studies), and AFib (1 of 3 studies). No studies found significant associations with cardiac death (1 study), total stroke death (1 study), ischemic stroke death (1 study), coronary revascularization (1 study), ventricular arrhythmia (1 study), SCD (2 studies), and incident hypertension (1 study). One study each analyzed MI death and ischemic stroke death and found a significant association.

## Observational Studies, Biomarkers

Five studies evaluated combined EPA + DHA $\pm$ DPA biomarkers, including adipose tissue, cholesteryl ester, erythrocyte, phospholipid, and plasma n-3 FA levels. Of the outcomes evaluated, none was analyzed by more than two studies. One study each found no significant association between various biomarker levels and MI, hemorrhagic stroke, total stroke (with a P value of 0.07 ), or cardiac death. One study found a significant association between higher phospholipid EPA+DHA+DPA and incident CHD. Another found a significant association between higher adipose EPA+DHA+DPA and acute coronary syndrome in men, but not in women. Two studies each evaluated CHF, ischemic stroke, and MACE. For each outcome only one of the studies found significant associations with EPA + DHA $\pm$ DPA biomarker levels. In one of the studies of CHF, phospholipid EPA+DHA+DPA level was associated with the outcome in women only but cholesteryl ester EPA+DHA+DPA levels were not associated in either sex.

* No reporting bias was detected for any outcome. All studies that measured n-3 FA intake were assessed to be direct, while all biomarker studies were assessed to be indirect.

Abbreviations: $C V D=$ cardiovascular disease, $\mathrm{DBP}=$ diastolic blood pressure, $\mathrm{DHA}=$ docosahexaenoic acid, $\mathrm{DPA}=$ docosapentaenoic acid, $\mathrm{EPA}=$ eicosapentaenoic acid, $\mathrm{HDL}-\mathrm{c}=$ high density lipoprotein cholesterol, LDL-C = low density lipoprotein cholesterol, MAP = mean arterial blood pressure, n-3 FA = omega-3 fatty acids, NA = not applicable, Obs = observational study, RCT = randomized controlled trial, SBP = systolic blood pressure, SoE = strength of evidence.

## EPA

For the most part, there is insufficient evidence regarding the effect of or association with EPA (specifically) and CVD clinical and intermediate outcomes (Table 49). There is low strength of evidence of no association between EPA intake and CHD and between EPA biomarkers and AFib; no RCTs evaluated these outcomes.

## Clinical Event Outcomes, RCTs

Regarding clinical event outcomes, one trial in an at risk population (dyslipidemia), found that after 5 years, compared with placebo, people taking purified EPA $1.8 \mathrm{~g} / \mathrm{d}$ had significantly lower risk of MACE and angina, but no significant difference in all-cause death, CHD death, coronary revascularization, SCD, or MI (also in the subgroup of people with prior CVD). Subgroup analysis for CHD death found no clear difference between those who also had CVD versus those without CVD.

## Intermediate Outcomes, RCTs

One trial of purified EPA $3.8 \mathrm{~g} / \mathrm{d}$ versus placebo found no significant effect on systolic BP, diastolic BP, or MAP. This trial and another of EPA $3.3 \mathrm{~g} / \mathrm{d}$ found no significant effect of EPA on LDL-c or HDL-c. Both trials, however, found significant net reductions in Tg concentration ( -42 and $-23 \mathrm{mg} / \mathrm{dL}$ ). The trial of EPA $3.8 \mathrm{~g} / \mathrm{d}$ also found a significant reduction in Total:HDL-c ratio ( -0.2 ).

## Observational Studies, Intake

Eight studies evaluated associations between estimated total EPA intake (specifically) and clinical outcomes. No outcome was evaluated by more than two studies. One study each found no significant association between EPA intake and acute coronary syndrome, ischemic stroke, or total stroke death. One study found a significant association between higher EPA intake and lower ischemic stroke death in healthy adults (in quantiles with median EPA intake $>0.07 \mathrm{~g} / \mathrm{d}$ in men and $>0.06 \mathrm{~g} / \mathrm{d}$ in women), but no association with hemorrhagic stroke death. One study found a significant association between higher EPA intake and lower risk of all-cause death ( $>0.01 \mathrm{~g} / \mathrm{d}$ ) in healthy adults. Another study found a significant association with MACE in healthy adults ( $>0.09 \mathrm{~g} / \mathrm{d}$ ). Two studies, each, found no significant associations between EPA intake and incident CHD (although $\mathrm{P}=0.06$ in one) or CHD death. For both incident hypertension and CVD death, one of two studies found significant associations between higher EPA ( $0.02 \mathrm{~g} / \mathrm{d}$ for hypertension and $0.01 \mathrm{~g} / \mathrm{d}$ for CVD death) intake and lower risk of outcomes; the other studies found no such associations.

## Observational Studies, Biomarkers

Ten studies evaluated associations between various EPA biomarkers and clinical outcomes. For three clinical outcomes, two of three studies found significant associations between higher EPA biomarker level and reduced risk of outcome. Three studies of healthy adults evaluated CHD, two of which found increased plasma or phospholipid EPA levels were associated with reduced CHD risk; the third study evaluated blood EPA levels. Three studies, two in healthy adults, one in people with hypercholesterolemia, evaluated MACE; the study of people with hypercholesterolemia found an association of reduced MACE risk with higher plasma EPA, as did one study of phospholipid EPA in healthy adults. The third study found no
significant association between erythrocyte EPA and MACE in healthy adults. Three studies, two in healthy adults, one in adults with a history of MI, evaluated CHF; in one study of healthy adults higher plasma EPA was associated with reduced CHF risk, but the other study of healthy adults found no association with phospholipid or cholesteryl ester EPA. The study in people with a history of MI also found an association with higher blood EPA. In this latter study, significant interactions were found for sex (no association was seen in women, in contrast with a significant association in men), statin use (those on statins had no association, in contrast with those on statins), and baseline HDL-c level (those with higher HDL-c had no association, in contrast with those with HDL-c $<40 \mathrm{mg} / \mathrm{dL}$ ). No interactions were found for age, use of angiotensin receptor blocker drugs, use of beta blocker drugs, diabetes, dyslipidemia, baseline LDL-c, hypertension, glomerular filtration function, or hypertriglyceridemia.

One of three studies found a significant association between higher EPA biomarkers (plasma EPA) and lower risk of death in healthy adults, but a second study of plasma EPA in healthy adults found no such association; nor did a study of blood EPA in people with a history of MI. One of two studies of plasma EPA in healthy adults found a significant association with CVD death. Two studies found no significant association between EPA biomarkers and ischemic stroke. One study found a significant association between erythrocyte EPA and incident hypertension. One study each found no associations between EPA biomarker levels and acute coronary syndrome, AFib, SCD, MI, hemorrhagic stroke, total stroke, cardiac death, CHD death, or total stroke death.

* No reporting bias was detected for any outcome. All studies that measured n-3 FA intake were assessed to be direct, while all biomarker studies were assessed to be indirect.

Abbreviations: CVD = cardiovascular disease, $\mathrm{DBP}=$ diastolic blood pressure, $\mathrm{EPA}=$ eicosapentaenoic acid, $\mathrm{HDL}-\mathrm{c}=$ high density lipoprotein cholesterol, LDL-c = low density lipoprotein cholesterol, MACE = major adverse cardiovascular events, MAP = mean arterial blood pressure, n3 FA = omega-3 fatty acids, NA = not applicable, Obs = observational study, RCT = randomized controlled trial, SBP = systolic blood pressure, SoE $=$ strength of evidence.

## DHA

For the most part, there is insufficient evidence regarding the effect of or association with EPA (specifically) and CVD clinical and intermediate outcomes (Table 50). There is moderate strength of evidence of no effect of purified DHA supplementation on BP or LDL-c and low strength of evidence of no association between DHA intake and incident CHD (from observational studies only).

## Clinical Event Outcomes, RCTs

No trial that reported clinical event outcomes evaluated DHA alone.

## Intermediate Outcomes, RCTs

Two trials compared purified DHA ( 3.6 and $2 \mathrm{~g} / \mathrm{d}$ ) to placebo and found no significant effects on systolic or diastolic BP. One of the trials also found no significant effect on MAP. Three trials of DHA (3.7, 3.6, or $2 \mathrm{~g} / \mathrm{d}$ ) also found no significant effect compared to placebo on LDL-c or HDL-c. Two of the trials ( 3.7 and $3.6 \mathrm{~g} / \mathrm{d}$ ) reported on Tg concentration changes and both found significant net reductions compared to placebo with DHA supplementation ( -27 and $-29 \mathrm{mg} / \mathrm{dL}$ ) . The trial of DHA $3.6 \mathrm{~g} / \mathrm{d}$ also found a significant reduction in Total:HDL-c ratio ( -0.3 ).

## Observational Studies, Intake

Eight studies evaluated the association between estimated total DHA intake (specifically) and risk of clinical outcomes. No study evaluated any outcome in more than two studies. Two studies found significant associations between higher DHA intake and lower risk of incident hypertension in healthy young adults (18-30 years old in one study; 39-54 year old women in a subgroup of one study), but not in an older subgroup in one study (55-89 years old). In the study of young adults, a significant association was found in quartiles with DHA intake $>0.06 \mathrm{~g} / \mathrm{d}$. One of two studies of healthy adults found an association of lower CVD death with DHA intake $>0.15 \mathrm{~g} / \mathrm{d}$. Two studies each found no association with CHD death or incident CHD (in populations with a broad range of ages, from 20-69 to 45-84 years old). One study each found significant associations of higher DHA intake with MACE ( $>0.15 \mathrm{~g} / \mathrm{d}$ DHA), ischemic stroke death ( $>0.15 \mathrm{~g} / \mathrm{d}$ ), and all-cause death ( $>0.02 \mathrm{~g} / \mathrm{d}$ ). In one study each, no associations were found with acute coronary syndrome, ischemic stroke, hemorrhagic stroke death, or total stroke death.

## Observational Studies, Biomarkers

Eleven studies evaluated various DHA biomarkers and their associations with clinical outcomes. A high proportion of association analyses were statistically significant favoring higher DHA biomarker levels. Four studies evaluated MACE (with various definitions); two found significant associations between higher DHA biomarker levels (phospholipid and adipose DHA) and lower risk of MACE in healthy adults. The other two studies found no association, one in hypercholesterolemic adults on statins (plasma DHA) and one in healthy adults (erythrocyte DHA). Two of three studies in healthy adults found significant associations between lower CHD risk and higher plasma or phospholipid DHA; the third study, also in healthy adults found no
association with blood DHA. Three studies evaluated CHF. One found associations between higher cholesteryl ester and phospholipid DHA and lower risk of incident CHF in healthy women, but not healthy men (whether the associations were significantly different between women and men was not reported). One study found that overall, there was no significant association with blood DHA in adults with a history of MI, but that there were significant associations in subgroups of people (where the difference in association between subgroups was at least nearly significant $[\mathrm{P}<0.10]$ ), such that significant association were found in people (after MI) not taking a statin ( P interaction with statin use $=0.003$ ), $\geq 65$ years old ( P interaction $=$ 0.051 ), with LDL-c $\geq 100 \mathrm{mg} / \mathrm{dL}$ ( P interaction $=0.068$ ), and with $\mathrm{HDL}-\mathrm{c} \leq 40 \mathrm{mg} / \mathrm{dL}$ ( P interaction $=0.096$ ). Three studies also evaluated all-cause death, two of which found significantly lower risk of death with higher plasma DHA (healthy adults) and blood DHA (in people with a history of MI who were not taking statins); another study of healthy adults found no association with plasma DHA.

Two studies found nonsignificant associations between higher cholesteryl ester DHA ( $\mathrm{P}=0.07$ ), phospholipid DHA ( $\mathrm{P}=0.08$ ), and plasma DHA ( $\mathrm{P}=0.052$ ) and lower risk of ischemic stroke in healthy adults. One study of healthy adults found an association between higher plasma DHA and lower risk of CVD death (both studies evaluated plasma DHA). One study each found significant associations between higher DHA biomarker levels and lower incidence of AFib, SCD, and CHD death (all plasma DHA in healthy adults). One study found a significant association between higher adipose DHA and lower risk of acute coronary syndrome in healthy men, but not healthy women. Another study found a significant association between higher erythrocyte DHA and lower risk of incident hypertension in healthy women aged 39 to 54 years, but not in women older than 54 years. One study found no significant associations between plasma DHA and both total stroke and total stroke death in healthy adults. One study, each, found no significant associations with MI, hemorrhagic stroke, or cardiac death.

* No reporting bias was detected for any outcome. All studies that measured n-3 FA intake were assessed to be direct, while all biomarker studies were assessed to be indirect.

Abbreviations: CVD = cardiovascular disease, DBP = diastolic blood pressure, DHA = docosahexaenoic acid, HDL-c = high density lipoprotein cholesterol, LDL-c = low density lipoprotein cholesterol, $\mathrm{MAP}=$ mean arterial blood pressure, $\mathrm{n}-3 \mathrm{FA}=$ omega-3 fatty acids, $\mathrm{NA}=$ not applicable, Obs = observational study, RCT = randomized controlled trial, $\mathrm{SBP}=$ systolic blood pressure, SoE = strength of evidence.

## DPA

Overall, there is insufficient evidence regarding effect of or association between DPA (specifically) and CVD clinical and intermediate outcomes (Table 51). There is low strength of evidence of no association between DPA biomarker levels and risk of AFib (from observational studies only).

## RCTs

No eligible RCTs compared purified DPA formulations versus placebo.

## Observational Studies, Intake

Two observational studies evaluated estimated total DPA intake (specifically). One study found no significant association between DPA intake and acute coronary syndrome in either healthy men or women. The other found significant associations between higher DPA intake and both incident CHD and MACE in healthy adults, in both instances with a significant association in the quartile with DPA intake $>0.04 \mathrm{~g} / \mathrm{d}$.

## Observational Studies, Biomarkers

Seven studies evaluated the association of various DPA biomarkers with clinical outcomes, all in healthy adults. No outcome was evaluated by more than three studies. One study in adults age $\geq 65$ years was the only study that evaluated several clinical outcomes. It found significant associations between higher plasma DPA and lower risks of all-cause and CVD death, nonsignificant associations with incident CHF ( $\mathrm{P}=0.057$ ) and total stroke death ( $\mathrm{P}=0.056$ ), but no significant associations with AFib, SCD, hemorrhagic, ischemic, or total stroke, or CHD death. For two outcomes, one of three studies found significant associations; one study found a significant association between blood DPA and incident CHD, but two found no associations with plasma or phospholipid DPA; one study found a significant association between adipose tissue DPA and MACE, but two found no associations with phospholipid or erythrocyte DPA. One study evaluated acute coronary syndrome and found a significant association in men with adipose tissue DPA, but not in women. One study evaluated incident hypertension and found a significant association of erythrocyte DPA in younger women (39-54 years old), but not older women (55-89 years old). One study found no significant association with cardiac death.

* No reporting bias was detected for any outcome. All studies that measured n-3 FA intake were assessed to be direct, while all biomarker studies were assessed to be indirect.

Abbreviations: CVD = cardiovascular disease, DBP = diastolic blood pressure, DPA = docosapentaenoic acid, HDL-c = high density lipoprotein cholesterol, LDL-c = low density lipoprotein cholesterol, MACE = major adverse cardiovascular events, MAP = mean arterial blood pressure, n-3 FA = omega-3 fatty acids, NA = not applicable, Obs = observational study, RCT = randomized controlled trial, SBP = systolic blood pressure, SoE = strength of evidence.

## SDA

Overall, there is insufficient evidence regarding effect of or association between SDA (specifically) and CVD clinical and intermediate outcomes (Table 52).

## RCTs

A single study compared $1.2 \mathrm{~g} / \mathrm{d}$ SDA to placebo in patients at risk for CVD and found no significant differences in change in systolic or diastolic BP, or LDL-c, HDL-c, or Tg at 6 weeks.

## Observational Studies

A single eligible observational study in healthy men evaluated baseline erythrocyte SDA and clinical outcomes. Erythrocyte SDA was not significantly associated with either MACE or cardiac death.

## Marine Oil FA Comparisons

There is insufficient evidence regarding comparisons of specific marine oil FA.

## Clinical Event Outcomes, RCTs

No trial that reported clinical event outcomes compared marine oil FA.

## Intermediate Outcomes, RCTs

Two trials that compared marine oil FA (EPA $3.8 \mathrm{~g} / \mathrm{d}$ vs. DHA $3.6 \mathrm{~g} / \mathrm{d}$; EPA+DHA 3.4 and $1.7 \mathrm{~g} / \mathrm{d}$ vs. EPA $1.8 \mathrm{~g} / \mathrm{d}$ ) found no significant differences in effect on BP, LDL-c, HDL-c, Tg, or Total:HDL-c ratio.

One trial compared $2.0 \mathrm{~g} / \mathrm{d}$ SDA and $1.9 \mathrm{~g} / \mathrm{d}$ EPA+DHA+DPA in healthy people. At 2 month followup, no significant differences in change in systolic or diastolic BP, or LDL-c, HDLc, Tg, Total:HDL-c, or LDL:HDL-c ratios were found.

#### Abstract

ALA There is moderate strength of evidence of no significant effect of ALA intake on BP, LDL-c, HDL-c, or Tg (Table 53). There is low strength of evidence of no association between ALA intake or biomarker level and CHD or CHD death, AFib, and CHF, each based primarily on observational studies; there was only a single or no RCTs evaluating these outcomes. There is insufficient evidence regarding other outcomes.

## Clinical Event Outcomes, RCTs

Two RCTs that evaluated ALA supplementation versus placebo reported clinical event outcomes, one in participants with CVD and one in healthy participants. All analyses were nonsignificant, for all-cause death (2 trials) and from one trial each, MACE, CVD death, cardiac death, CHD death, CHF death, total MI, incident angina, total stroke, ventricular arrhythmia, and SCD. Within-study subgroup analyses revealed no significant differences in effect for various subgroups for MACE (1 trial) or with or without diabetes for CHD death (1 trial).

## Intermediate Outcomes, RCTs

Five ALA RCTs evaluated BP, with doses ranging from 1.4 to $5.9 \mathrm{~g} / \mathrm{d}$ for 1 to 3.4 years. All found no significant effect on systolic or diastolic BP, mostly with wide confidence intervals. One of the trials found no significant difference in effect on BP between those with hypertension and the study population as a whole. Another trial found no significant difference in effect between 1.4 and $5.9 \mathrm{~g} / \mathrm{d}$ ALA. No trial reported on MAP.

Five trials reported no significant effects of ALA on LDL-c, HDL-c, Tg, or Total:HDL-c ratio (3 trials). No differences in effect were found in the one trial that compared 1.4 and $5.9 \mathrm{~g} / \mathrm{d}$ ALA. No trial reported on LDL:HDL-c ratio.

## Observational Studies, Intake

Thirteen observational studies evaluated ALA intake. One of these was a pooling of 11 prior studies (the pooled studies were not included in duplicate for the outcomes evaluated by the pooling study). The large majority of analyses found no significant associations; only two studies found any significant associations between higher ALA intake and clinical outcomes.

By meta-analysis, overall there is no statistically significant association between ALA intake and CHD death across a median dose range of 0.59 to $2.5 \mathrm{~g} / \mathrm{d}$ (effect size per g/d $=0.95$ [ $95 \%$ CI 0.87 to 1.04$]$ ]. Meta-analyses with the addition of a spline knot point at different dose thresholds (from 0.1 to $1.2 \mathrm{~g} / \mathrm{d}$ ) consistently found a stronger association (of higher dose being associated with lower risk at higher doses than at lower doses (ES above knot < ES below know), but at several knot points this difference was marginal. This implies the possibility of a floor effect (where intake above a certain minimum amount is needed before any benefit accrues). However, at no dose threshold was there a statistically significant difference between the ES above the dose threshold (knot) and below the threshold. The best fit curve was found with a knot at $0.9 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at $1.2 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.41)$, the highest dose threshold that could be tested.

By meta-analysis, overall there is no association between ALA intake and CHD across a median dosage range of 0.2 to $2.5 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.98$ [95\% CI 0.93 to 1.04]). Metaanalyses with the addition of a spline knot point at different dose thresholds (from 0.5 to $1.4 \mathrm{~g} / \mathrm{d}$ ) consistently found marginally smaller ES at lower doses than at higher doses. At no dose
threshold was there a statistically significant difference between the ES below the dose threshold (knot) and above the threshold. The best fit curve was found with a knot at $0.6 \mathrm{~g} / \mathrm{d}$. The lowest P value between lower-dose and higher-dose ES estimates was found at $0.5 \mathrm{~g} / \mathrm{d}(\mathrm{P}=0.28)$.

Two studies both found significant associations between higher ALA intake and reduced all-cause death (>2.2 g/d in healthy adults; also in healthy men but insufficient data were reported regarding a dose threshold). One of two studies found a significant association between higher ALA intake ( $>0.6 \mathrm{~g} / \mathrm{d}$ ) and lower risk of SCD in healthy women but not in a subset of women with CVD; the second study found no significant association in healthy adults. One of two studies found a significant association between higher ALA intake (unclear threshold) and lower risk of CVD death in younger men (35-57 years old), but another study found no association in older men ( $\geq 65$ years old). For all other analyzed clinical outcomes, no significant associations were found with ALA intake, including CHF (4 studies), CVD (3 studies), MACE (2 studies), hemorrhagic and ischemic stroke (2 studies each), AFib (1 study), and hypertension (1 study).

## Observational Studies, Biomarkers

Eight studies evaluated various ALA biomarkers. Almost all analyses found no significant associations between ALA biomarkers and clinical outcomes. No outcome was evaluated by more than three studies. For CHF, one of three studies found a significant association between higher plasma ALA in healthy men, but two other studies found no significant associations in healthy adults with plasma, cholesteryl ester, or phospholipid ALA. One of two studies found a significant association between higher plasma ALA and lower risk of CVD death, but the other study found no significant association also with plasma ALA in healthy adults. No significant associations were found for ischemic stroke ( 3 studies), incident CHD, hemorrhagic and total stroke (2 studies each), MACE (2 studies), all-cause death (2 studies), or AFib, SCD, incident hypertension, cardiac death, or CHD death (1 study each).

Table 53. Evidence profile for the effect and association of ALA with CVD outcomes*

Table 53. Evidence profile for the effect and association of ALA with CVD outcomes (continued)

| Outcome | SoE Grade | Design <br> No. Studies | Study <br> Limitations | Consistency |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

* No reporting bias was detected for any outcome. All studies that measured n-3 FA intake were assessed to be direct, while all biomarker studies were assessed to be indirect.

Abbreviations: $\mathrm{ALA}=$ alphalinolenic acid, $\mathrm{CVD}=$ cardiovascular disease, $\mathrm{DBP}=$ diastolic blood pressure, $\mathrm{HDL}-\mathrm{C}=$ high density lipoprotein cholesterol, LDL-c = low density lipoprotein cholesterol, MAP = mean arterial blood pressure, n-3 FA = omega-3 fatty acids, NA = not applicable, Obs = observational study, RCT = randomized controlled trial, SBP = systolic blood pressure, SoE = strength of evidence.

## Marine Oil Versus ALA

There is insufficient evidence of direct comparisons between marine oil and ALA intake on CVD outcomes. Across studies, the comparison between marine oil and ALA is unclear, largely because of insufficient evidence regarding ALA; however, where there is high strength of evidence of significant effects of marine oil on improving Tg and HDL-c, there is moderate strength of evidence of no effect of ALA intake on these intermediate outcomes.

## Clinical Event Outcomes, RCTs

No trial that reported clinical event outcomes directly compared marine oils and ALA.

## Intermediate Outcomes, RCTs

One trial that compared two doses of EPA+DHA ( 1.7 and $0.8 \mathrm{~g} / \mathrm{d}$ ) with ALA $4.5 \mathrm{~g} / \mathrm{d}$ found no differences in systolic or diastolic BP at 4 months. Across trials, regardless of n-3 FA type, there was no evidence of an effect of BP; no difference in effect was apparent between marine oil and ALA trials.

Two trials that compared EPA+DHA ( 0.8 and $1.7 \mathrm{~g} / \mathrm{d}$ in one trial, $0.4 \mathrm{~g} / \mathrm{d}$ in the other) to ALA (4.5 [rapeseed oil margarine] and $2 \mathrm{~g} / \mathrm{d}$ ["plant oil" margarine], respectively) for 6 months and 3.4 years found no differences between n-3 FA types for LDL-c, HDL-c, or Tg. Neither trial reported on lipid ratios. No evident differences were found across trials between marine oils and ALA for their (nonsignificant) effects on LDL-c and HDL-c. In contrast with the two trials that directly compared EPA+DHA and ALA, 32 marine oil (versus placebo) trials fairly consistently found significant effect on Tg reduction in contrast with the four ALA (versus placebo) trials, which mostly had imprecise estimates of effects on Tg.

## Subgroup Analyses Summary

Overall, 24 RCTs $^{46,58,70,76,85, ~ 89, ~ 90, ~ 94, ~ 96, ~ 97, ~ 99, ~ 115, ~ 119, ~ 123, ~ 128, ~ 146, ~ 147, ~ 150, ~ 156, ~ 157, ~ 160, ~ 166, ~ 167, ~ 179, ~}$ ${ }^{195}$ and 9 observational studies ${ }^{72,83,102,148,154,159,162,171,181}$ reported on subgroup (or factorial) analyses. For most outcomes, there is insufficient evidence regarding differential effects (or associations) in different subgroups of study participants evaluated within studies. Metaregression results across studies are summarized in the summary by n-3 FA, above. (In brief, only for the effect of marine oil on Tg was there an indication across studies of interactions by dose and baseline Tg, with larger effects with higher dose and higher baseline Tg.) Among outcomes with sufficient RCT data to allow meta-analysis, no discernable difference in effect was found across trials based on publication year.

Twenty-two subgroup analyses by sex were reported ( 10 with ALA, 11 with marine oil, 1 with total n-3 FA). One of three RCTs of marine oil on MACE found a greater beneficial effect of n-3 FA in women (HR [supplement vs. placebo] $=0.82$ in women vs. 1.04 in men; P interaction $=0.04$ ). One of three observational studies of CHF found a stronger association with between higher blood EPA and lower risk of CHF in men than women (HR [lower intake vs. higher intake] $=5.82$ in men vs. 0.69 in women; P interaction $=0.008$ ), but no interaction with blood DHA. One RCT found a stronger effect on lowering Tg of supplementation with higherdose marine oil ( $1.8 \mathrm{~g} / \mathrm{d}$ ) in men than in women (difference not reported; P interaction $=0.038$ ),
but this interaction was not found with lower-dose marine oil ( $0.7 \mathrm{~g} / \mathrm{d}$ ). All 19 other analyses were not statistically significant (or no statistical difference was reported).

Twenty subgroup analyses by statin use were reported ( 1 with ALA, 19 with marine oil). All but one study found difference in effect or association based on statin use. One study found a stronger association between higher blood DHA and, separately, higher blood EPA, and lower risk of CHF in those not using statins; DHA: HR [lower intake vs. higher intake] = 6.65 (without statins) vs. 0.74 (with statins), P interaction = 0.003; EPA: HR [lower intake vs. higher intake] = 6.40 (without statins) vs. 1.45 (with statins), P interaction $=0.048$. A relatively small number of RCTs of lipoproteins (LDL-c and HDL-c) and Tg analyzed interactions between n-3 FA and statins and found no interaction between statin use and the effect of marine oil supplementation on lipids (LDL-c 5 RCTs, Tg 4 RCTs, HDL-c 3 RCTs). No studies explicitly compared the interaction of n-3 FA intake (or biomarker level) with aspirin intake on outcomes.

Sixteen subgroup analyses comparing those with and without diabetes were reported (6 with ALA, 10 with marine oil). Two RCT analyses reported only that a statistically significant effect of n-3 FA was found among participants with diabetes but no significant effect was found those without diabetes (marine oil and CHD death, ALA and ventricular arrhythmia). All other analyses reported no difference in effect or association based on diabetes status.

## Summary by Key Question

## Key Question 1

What is the efficacy or association of n-3 FA (EPA, DHA, EPA $+D H A, D P A, S D A, A L A$, or total n-3 FA) exposures in reducing CVD outcomes (incident CVD events, including all-cause death, CVD death, nonfatal CVD events, new diagnosis of CVD, peripheral vascular disease, CHF, major arrhythmias, and hypertension diagnosis) and specific CVD risk factors (BP, key plasma lipids)?

- Total n-3 FA
o Overall, there is insufficient evidence regarding the effect of or association between total n-3 FA (combined ALA and marine oils) and clinical or intermediate outcomes. There is low strength of evidence of no association between total n-3 FA intake and stroke death, and total (fatal and nonfatal) MI (each association based on longitudinal observational studies of dietary intake).
o For each outcome there was no consistent (and replicated) significant association between total n-3 FA intake and risk reduction.
- Marine oils
o There is high strength of evidence from RCTs that marine oils clinically and statistically significantly lower Tg. There is also evidence that they statistically, but arguably not clinically, significantly raise HDL-c, but lower LDL-c. Finally, there is high strength of evidence that marine oil supplementation significantly lowers Total:HDL-c ratio.
o There is high strength of evidence of that marine oils statistically significantly lower Tg —possibly with greater effects with higher doses and in people with higher baseline Tg -and statistically significantly raise HDL-c and LDL-c by similar amounts. There is also high strength of evidence that marine oil significantly lowers Total:HDL-c ratio
o There is low strength of evidence that marine oil significantly lowers risk of ischemic stroke.
o There is a high strength of evidence of no effect of marine oil on risk of MACE, all-cause death, SCD, revascularization, and BP; moderate strength of evidence of no effect of marine oil on risk of AFib; and low strength of evidence of no effect of marine oil on risk of CVD death, CHD death, total CHD, MI, angina pectoris, CHF, total stroke, and hemorrhagic stroke. There is insufficient evidence for other outcomes.
- Marine oils, EPA
o There is insufficient evidence regarding the effect of or association with EPA (specifically) and most CVD clinical and intermediate outcomes. There is low strength of evidence of no association between EPA intake and CHD and between EPA biomarkers and AFib.
- Marine oils, DHA
o For the most part, there is insufficient evidence regarding the effect of or association with DHA and CVD clinical and intermediate outcomes. There is moderate strength of evidence of no effect of purified DHA supplementation on BP or LDL-c and low strength of evidence of no association between DHA intake and incident CHD (from observational studies).
- Marine oils, DPA
o Overall, there is insufficient evidence regarding effect of or association between DPA (specifically) and most CVD clinical and intermediate outcomes. There is low strength of evidence of no association between DPA biomarker levels and risk of AFib.
- SDA
o Overall, there is insufficient evidence regarding effect of or association between SDA (specifically) and CVD clinical and intermediate outcomes.
- ALA
o There is moderate strength of evidence of no significant effect of ALA intake on BP, LDL-c, HDL-c, or Tg. There is low strength of evidence of no association between ALA intake or biomarker level and CHD or CHD death, AFib, and CHF, each based on observational studies. There is insufficient evidence regarding other outcomes.

## Key Question 1, Subquestions

1.1.1. What is the efficacy or association of n-3 FA in preventing CVD outcomes in people without known CVD (primary prevention )?

- There was insufficient evidence for cardiac death, CHF death, ischemic stroke death, hemorrhagic stroke death, revascularization, acute coronary syndrome, angina pectoris, ventricular arrhythmia, incident hypertension, TC/HDL-c ratio, and LDL-c/HDL-c ratio.
- There was insufficient RCT evidence and inconsistent observational evidence for CHD death, MI death, all-cause death, total MI, and SCD.
- There was insufficient RCT evidence but observational evidence of no association for MACE, CVD death, total stroke death, incident CHD, total stroke, ischemic stroke, hemorrhagic stroke, AFib, and CHF.
- There was strong RCT evidence for no effect for BP (systolic and diastolic), MAP (only 3 trials), LDL-c, and HDL-c.
- There was strong RCT evidence for a significant protective effect for Tg .
1.1.2. What is the efficacy or association of n-3 FA in preventing CVD outcomes in people at high risk for CVD (primary prevention)?
- There was insufficient evidence for CVD death, cardiac death, CHD death, MI death, CHF death, total stroke death, ischemic stroke death, hemorrhagic stroke death, incident CHD, revascularization, acute coronary syndrome, angina pectoris, total stroke, ischemic stroke, hemorrhagic stroke, SCD, AFib, ventricular arrhythmia, CHF, incident hypertension, and MAP.
- There was inconsistent RCT evidence for total MI.
- There was strong RCT evidence for no effect for MACE, all-cause death, BP (systolic and diastolic), LDL-c, HDL-c, TC/HDL-c ratio, and LDL-c/HDL-c ratio.
- There was strong RCT evidence for a significant protective effect for Tg.
1.1.3. What is the efficacy or association of n-3 FA in preventing CVD outcomes in people with known CVD (secondary prevention)?
- There was insufficient evidence for MI death, CHF death, total stroke death, ischemic stroke death, hemorrhagic stroke death, CHD, acute coronary syndrome, angina pectoris, ischemic stroke, hemorrhagic stroke, ventricular arrhythmia, incident hypertension, MAP, TC/HDL-c ratio, and LDL-c/HDL-c ratio.
- There was inconsistent RCT evidence for CVD death and cardiac death. There was RCT evidence of no effect for MACE, CHD death, all-cause death, total MI, revascularization, total stroke, SCD, AFib, and CHF.
- There was strong RCT evidence of no effect for BP (systolic and diastolic) and LDL-c.
- There was strong RCT evidence of a protective effect for HDL-c and Tg.
1.2. What is the relative efficacy of different n-3 FA on CVD outcomes and risk factors?
- There is low strength of evidence of no difference between EPA+DHA and its individual components.
- There is low strength of evidence of greater efficacy of marine oils over ALA.
1.3. Can the CVD outcomes be ordered by strength of intervention effect of n-3 FA ?
- Based on the summary effect sizes of meta-analyzed RCTs, marine oils had no significant effect on CVD outcomes. The order of effect sizes of CVD outcomes with sufficient data to allow meta-analysis, was MI ( $\mathrm{ES}=0.88$ ), CVD death ( $\mathrm{ES}=0.92$ ), MACE ( $\mathrm{ES}=0.96$ ), allcause death ( $\mathrm{ES}=0.97$ ), total stroke ( $\mathrm{ES}=0.98$ ), and $\mathrm{SCD}(\mathrm{ES}=1.04)$.

## Key Question 2

n-3 FA variables and modifiers
2.1. How does the efficacy or association of n-3 FA in preventing CVD outcomes and with CVD risk factors differ in subpopulations, including men, premenopausal women, postmenopausal women, and different age or race/ethnicity groups?

- There was insufficient evidence to assess the efficacy or association of n-3 FA in preventing CVD outcomes and with CVD risk factors in subgroups based on race/ethnicity and whether women were pre- or postmenopausal.
- 5 studies (mostly observational) found no significant differences in association based on age, with cutoffs for subgroups ranging between 60 and 70 years of age.
- Two studies found no interaction with age as a continuous variable. One trial found a significant difference in favor of women, two observational studies found a significant difference in favor of men, and 9 studies (mix of RCT and observational) found no difference between men and women.
2.2 What are the effects of potential confounders or interacting factors-such as plasma lipids, body mass index, BP, diabetes, kidney disease, other nutrients or supplements, and drugs (e.g., statins, aspirin, diabetes drugs, hormone replacement therapy)?
- There was insufficient evidence to assess the following potential confounders or interacting factors: beta-blocker use, baseline HDL-c, glargine use, nitrate use, digoxin use, diuretic use, eGFR, ACEi use, anticoagulant use, total cholesterol levels, or use of fish oil supplements.
- There was inconsistent evidence for the following potential confounders or interacting factors: triglyceride levels, statin use, b-vitamin use, and baseline LDL-c.
- There was evidence of no interactions with body mass index, hypertension status, diabetes status, and baseline TC/HDL-c ratio.
2.3 What is the efficacy or association of different ratios of n-3 FA components in dietary supplements or biomarkers on CVD outcomes and risk factors?
- No study directly compared efficacy or association of different ratios of n-3 FA components on outcomes. Across studies, there were insufficient data to make these assessments.
2.4 How does the efficacy or association of n-3 FA on CVD outcomes and risk factors differ by ratios of different n-3 FA—DHA, EPA, and ALA, or other n-3 FA?
- No study directly compared efficacy or association of different ratios of n-3 FA components on outcomes. Across studies, there were insufficient data to make these assessments.
2.5 How does the efficacy or association of n-3 FA on CVD outcomes and risk factors differ by source (e.g., fish and vs. seafood, common plant oils (e.g., soybean vs,, canola), fish oil supplements, fungal-algal supplements, flaxseed oil supplements)?
- No study directly compared efficacy or association of different sources of n-3 FA on outcomes. Across studies, there were insufficient data to make these assessments.
2.6 How does the ratio of n-6 FA to n-3 FA intakes or biomarker concentrations affect the efficacy or association of n-3 FA on CVD outcomes and risk factors?
- No trial or observational studies evaluated n-6 FA to n-3 FA intake concentrations and no differences across studies by this ratio was evident.
2.7 Is there a threshold or dose-response relationship between n-3 FA exposures and CVD outcomes and risk factors? Does the study type affect these relationships?
- Among trials, for all clinical CVD outcomes there is insufficient evidence regarding a dose-response relationship within or between trials.
- For BP, LDL-c, and HDL-c, trials do not find significant differences in effect by marine oil dose either within or between trials.
- Trials comparing marine oil doses mostly found no significant difference between higher and lower dose marine oils. However, a possible pattern could be discerned such that higher doses of 3.4 or $4 \mathrm{~g} / \mathrm{d}$ reduced Tg by at least $30 \mathrm{mg} / \mathrm{dL}$ more than lower doses of 1 to $2 \mathrm{~g} / \mathrm{d}$. Higher doses $\leq 3 \mathrm{~g} / \mathrm{d}(1.7-3 \mathrm{~g} / \mathrm{d})$ yielded much smaller relative differences in Tg change compared to lower doses ( $0.7-2.25 \mathrm{~g} / \mathrm{d}$ ). By metaregression, each increase of EPA + DHA dose by $1 \mathrm{~g} / \mathrm{d}$ was associated with a greater net change Tg of $-5.9 \mathrm{mg} / \mathrm{dL}$ ( $95 \%$ CI -9.9 to-2.0; $\mathrm{P}=0.003$ ); no inflection point was found above which the association plateaued.
- Metaregressions of observational studies yielded the following conclusions:
o For all-cause death, there may be a ceiling effect at about $0.2 \mathrm{~g} / \mathrm{d}$, such that increasing marine oil intake up to this level may be associated with lower allcause death, but increasing intake above this level may not be associated with further decreased risk.
o For total stroke, ischemic stroke, and CHF, at lower ranges of intake there were statistically significant associations between higher marine oil intake level and lower risk of outcome, in contrast to associations found at higher ranges of intake. However, the associations at lower and higher doses were not statistically significant from each other. For ischemic stroke, associations between higher doses and risk of stroke were stronger and statistically significant across lower doses than at higher doses (with thresholds between lower and higher doses from 0.1 and $0.4 \mathrm{~g} / \mathrm{d}$ ) and the differences in associations between lower and higher doses were statistically significant. Any dose inflection point that may exist is likely to be beyond the range of testable thresholds (i.e., >0.4 g/d). Similarly, for CHF significant associations were found at lower doses, in contrast to at higher doses, with thresholds ranging from 0.1 to $0.5 \mathrm{~g} / \mathrm{d}$, and the differences were statistically significant at most thresholds. Any dose inflection point that may exist is likely to be beyond the range of testable thresholds (i.e., $>0.5 \mathrm{~g} / \mathrm{d}$ ).
0 For CVD death, CHD death, total CHD, and hemorrhagic stroke, there were no apparent differences in association between marine oil intake dose and outcome at lower or higher dose ranges.
o For CHD death and CHD, there were no apparent differences in association between ALA intake dose and outcome at lower or higher dose ranges.
2.8 How does the duration of intervention or exposure influence the effect of n-3 FA on CVD outcomes and risk factors?
- None of the meta-regressions found a significant interaction for follow-up time. No difference in effect was found within studies at different durations of intervention. Observational studies did not evaluate differences in duration of exposure.
2.9 What is the effect of baseline n-3 FA status (intake or biomarkers) on the efficacy of n-3 FA intake or supplementation on CVD outcomes and risk factors?
- No study found a significant difference in subgroups based on baseline fish or n-3 FA intake.

## Key Question 3

Adverse events
3.1 What adverse effects are related to n-3 FA intake (in studies of CVD outcomes and risk factors)?

- No serious or severe adverse events were related to n-3 FA intake (supplementation).

Most reported adverse events were mild and gastrointestinal in nature; however, only 2 of 25 trials reported statistically significant differences in adverse events between n-3 FA supplements and placebo.
3.2 What adverse events are reported specifically among people with CVD or diabetes (in studies of CVD outcomes and risk factors)?

- Among 10 trials of patients with CVD (9 with marine oil, 1 with total n-3 FA, 2 with ALA), either no adverse events or no significant difference between n-3 FA and placebo were reported.
- A single study reported adverse events from a trial of people with diabetes, finding no significant differences in serious or nonserious adverse events between marine oil and placebo.

## Discussion

## Overall Summary of Key Findings

In this systematic review we identified 61 eligible randomized controlled trials (RCT)s (in 82 publications) and 37 eligible prospective longitudinal and nested case-control studies (in 65 publications) for inclusion based on prespecified eligibility criteria. Most of the 19 RCTs that evaluated the effects of marine oil supplements (eicosapentaenoic acid [EPA] + docosahexaenoic acid [DHA]) compared with placebo on clinical cardiovascular disease (CVD) outcomes in populations at risk for CVD or with CVD, while most of the observational studies examined the associations between intake of various individual omega-3 fatty acids (n-3 FA) and in combination with each other in relationship to long-term CVD events in generally healthy populations. The RCTs of intermediate CVD outcomes (blood pressure [BP] and lipids) were conducted in all three populations of interest (generally healthy, at risk for CVD—primarily due to dyslipidemia, or with CVD). Only a single observational study evaluated BP; none evaluated lipids.

The main findings of the studies, regarding effect or association of higher n-3 FA intake or biomarker level and outcomes are summarized in the following tables. Table 54 includes analyses of n-3 FA and outcome pairs for which there is evidence to support an effect or association of higher n-3 FA intake and risk of a CVD outcome or on a CV risk factor. These include high strength of evidence that higher marine oil intake statistically significantly raises high density lipoprotein cholesterol (HDL-c), lowers triglycerides (Tg) concentration and Total:HDL-c ratio, but also raises low density lipoprotein cholesterol (LDL-c). There is low strength of evidence that higher marine oil intake is associated with lower risk of ischemic stroke.

Table 55 includes analyses of n-3 FA and outcome pairs for which there is evidence supporting no effect or association of n-3 FA intake (or biomarker level) and outcomes. These include high strength of evidence for no effect of or association between marine oil intake and major adverse cardiac events (MACE), all-cause mortality, sudden cardiac death (SCD), coronary revascularization, or BP; moderate strength of evidence of no association between marine oil intake and atrial fibrillation (AFib), and between DHA intake and BP or LDL-c, and between alphalinolenic acid (ALA) and BP, LDL-c, HDL-c, or Tg; and low strength of evidence of no association between total n-3 FA intake and stroke death or myocardial infarction (MI); between marine oil intake and CVD death, coronary heart disease (CHD) death, total CHD, MI, angina pectoris, CHF, total stroke or hemorrhagic stroke; between EPA intake and CHD; between EPA biomarkers and AFib; between DHA intake and CHD; between docosapentaenoic acid (DPA) biomarkers and AFib; and between ALA intake and CHD, CHD death, AFib, or CHF. Analyses of n-3 FA and outcome pairs not included in the table provided insufficient evidence.

Table 54. Main findings of high, moderate, or low strength of evidence of significant effects or associations between omega-3 fatty acids and outcomes
There is high strength of evidence for the following effects or associations of higher n-3 FA intake or biomarker levels and lower cardiovascular disease (CVD) risks or events:

- Marine oil* supplementation (or increased intake) and an increase in HDL-c
o RCTs (of mostly supplements)
o Summary net change in HDL-c: $0.9 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI} 0.2,1.6)$
- Marine oil* supplementation (or increased intake) and a decrease in Tg
o RCTs (of mostly supplements)
o Summary net change in Tg: $-24 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{Cl}-31,-18)$
- Marine oil* supplementation (or increased intake) and a decrease in total cholesterol to HDL-c ratio
o RCTs (of mostly supplements)
o Summary net change in Total:HDL-c ratio: -0.17 ( $95 \% \mathrm{Cl}-0.26,-0.09$ )
There is high strength of evidence for the following effects or associations of higher n-3 FA intake or biomarker levels and higher CVD risk:
- Marine oil* supplementation (or increased intake) and an increase in LDL-c
o RCTs (of mostly supplements)
o Summary net change in LDL-C: $2.0 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{Cl} 0.4,3.6$ )
There is low strength of evidence for the following effects or associations of higher n-3 FA intake and lower CVD risks or events:
- Marine oil* higher dietary intake and a lower risk of ischemic stroke
o Observational studies (of total dietary intake), significant by metaregression: 0.51 ( $95 \% \mathrm{CI} 0.29$, 0.89) per g/d
* Statements about "marine oil" are based on all evidence of analyses of EPA+DHA+DPA, EPA+DHA, EPA, DHA, and DPA as supplements (e.g., fish oil) or as components of dietary intake (e.g., from fatty fish).

Abbreviations: CHD = coronary heart disease (also known as coronary artery disease), CHF = congestive heart failure, $\mathrm{CI}=$ confidence interval, CVD = cardiovascular disease, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HDL-c = high density lipoprotein cholesterol, HR = hazard ratio, LDL-c = low density lipoprotein cholesterol, n-3 FA = omega-3 fatty acids, RCT = randomized controlled trial, Tg = triglycerides.

Table 55. Main findings of high, moderate, or low strength of evidence of no significant effects or associations between omega-3 fatty acids and outcomes
There is high strength of evidence of no effect or association of n-3 FA intake or biomarker level and the following outcomes:

- Marine oil* supplementation (or increased dietary intake) and risk of major adverse cardiovascular event (MACE)
o RCTs (of mostly supplements); observational studies (of total dietary intake) also found no significant associations
o Summary effect size (RCTs): 0.96 ( $95 \% \mathrm{CI} 0.91,1.02$ )
- Marine oil* supplementation (or increased dietary intake) and all-cause death
o RCTs (of mostly supplements) supported by observational studies (of total dietary intake)
o Summary effect size (RCTs): 0.97 ( $95 \% \mathrm{CI} 0.92,1.03$ )
o Observational studies (of total dietary intake): 0.62 ( $95 \% \mathrm{Cl} 0.31,1.25$ ) per g/d
- Marine oil* supplementation (or increased dietary intake) and sudden cardiac death (SCD)
o RCTs (of mostly supplements) supported by an observational study (of total dietary intake)
o Summary effect size (RCTs): 1.04 ( $95 \% \mathrm{CI} 0.92$, 1.17)
- Marine oil* supplementation (or increased dietary intake) and coronary revascularization
o RCTs (of mostly supplements) supported by an observational study (of total dietary intake)
- Marine oil* supplementation (or increased dietary intake) and systolic or diastolic blood pressure
o RCTs (of mostly supplements)
o Summary net change in systolic blood pressure: $0.1 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.2,0.4)$
o Summary net change in diastolic blood pressure: $-0.2 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.4,0.5)$
There is moderate strength of evidence of no effect or association of n-3 FA intake or biomarker level and the following outcomes:
- Marine oil* supplementation (or increased dietary intake) and atrial fibrillation
o RCTs (of mostly supplements); observational studies of intake were inconsistent
- Purified DHA supplementation and systolic or diastolic blood pressure
o RCTs (of supplements only)
- Purified DHA supplementation and LDL-c
o RCTs (of supplements only)
- ALA supplementation (or increased dietary intake) and systolic or diastolic blood pressure
o RCTs (of mostly supplements)
- ALA supplementation (or increased dietary intake) intake and LDL-c, HDL-c, and Tg
o RCTs (of mostly supplements)

Table 55. Main findings of high, moderate, or low strength of evidence of no significant effects or associations between omega-3 fatty acids and outcomes, continued
There is low strength of evidence of no effect or association of n-3 FA intake or biomarker level and the following outcomes:

- Total n-3 FA higher dietary intake and stroke death
o Observational studies (of total dietary intake and biomarkers)
- Total n-3 FA higher dietary intake and myocardial infarction
o Observational studies (of total dietary intake)
- Marine oil* supplementation (or increased dietary intake) and cadiovascular disease (CVD) death
o Summary effect size (RCTs): 0.92 ( $95 \% \mathrm{Cl} 0.82,1.02)^{\dagger}$
o Observational studies (of total dietary intake): 0.88 ( $95 \% \mathrm{Cl} 0.82,0.95$ ) per g/d
- Marine oil* supplementation (or increased dietary intake) and coronary heart disease (CHD) death
o RCTs (of mostly supplements) imprecise
o Observational studies (of total dietary intake): 1.09 ( $95 \% \mathrm{Cl} 0.76,1.57$ ) per g/d
- Marine oil* higher dietary intake and coronary heart disease (CHD)
o Observational studies (of total dietary intake), supported by a single study of n-3 FA biomarkers
o Observational studies (of total dietary intake): 0.94 ( $95 \% \mathrm{Cl} 0.81,1.10$ ) per g/d
- Marine oil* supplementation (or increased dietary intake) and myocardial infarction
o Summary effect size (RCTs): 0.88 ( $95 \% \mathrm{Cl} 0.77,1.02)^{\dagger}$
- Marine oil* supplementation and angina pectoris
o RCTs (of supplements) with heterogeneous outcomes (definitions of angina pectoris)
- Marine oil* supplementation (or increased dietary intake) and congestive heart failure (CHF)
o RCTs (of mostly supplements) imprecise and could not be meta-analyzed, all nonsignificant
o Observational studies (of total dietary intake) significant by metaregression: 0.76 ( $95 \% \mathrm{Cl} 0.58$, $1.00)$ per g/d ( $\mathrm{P}<0.05$ )
- Marine oil* supplementation (or increased dietary intake) and total stroke (fatal and nonfatal ischemic and hemorrhagic stroke)
o Summary effect size (RCTs): 0.97 ( $95 \% \mathrm{CI} 0.83,1.13$ )
o Observational studies (of total dietary intake): 0.68 ( $95 \% \mathrm{Cl} 0.53,0.87$ ) per g/d
- Marine oil* higher dietary intake and hemorrhagic stroke
o Observational studies (of total dietary intake): 0.61 ( $95 \% \mathrm{Cl} 0.34,1.11$ ) per g/d
- EPA higher dietary intake and CHD
o Observational studies (of total dietary intake)
- EPA higher biomarker levels and atrial fibrillation
o Observational studies (of biomarkers)
- DHA higher dietary intake and CHD
o Observational studies (of total dietary intake and biomarkers)
- DPA higher biomarker levels and atrial fibrillation
o Observational studies (of biomarkers)
- ALA higher dietary intake and CHD death and, separately, total CHD
o Observational studies (of total dietary intake); CHD death finding supported by one RCT (of supplementation) and one observational study of biomarkers
o Observational studies (of total dietary intake): CHD death 0.94 ( $95 \% \mathrm{CI} 0.85,1.03$ ) per $\mathrm{g} / \mathrm{d}$
o Observational studies (of total dietary intake): CHD 0.97 ( $95 \% \mathrm{Cl} 0.92,1.03$ ) per g/d
- ALA higher dietary intake and atrial fibrillation
o Observational studies (of total dietary intake and biomarkers)
- ALA supplementation (or increased dietary intake) and congestive heart failure (CHF)
o Observational studies (of total dietary intake and biomarkers), supported by one RCT (of supplementation)
* Statements about "marine oil" are based on all evidence of analyses of EPA+DHA+DPA, EPA+DHA, EPA, DHA, and DPA as supplements (e.g., fish oil) or as components of dietary intake (e.g., from fatty fish).
$\dagger$ There is low confidence that this summary estimate would remain suggestive of no effect with the addition of future trial data (and greater statistical power).

Abbreviations: ALA = alphalinolenic acid, CHD = coronary heart disease, CHF = congestive heart failure, DHA = docosahexaenoic acid, DPA = docosapentaenoic acid, EPA = eicosapentaenoic acid, HDL-c = high density lipoprotein cholesterol, LDL-C = low density lipoprotein cholesterol, MACE = major adverse cardiovascular event (including cardiac and stroke events and death; variously defined by studies), n-3 FA = omega-3 fatty acids, RCT = randomized controlled trial, $\mathrm{SCD}=$ sudden cardiac death, $\mathrm{Tg}=$ triglycerides.

Studies within each category of analysis (by study design and by n-3 FA) were diverse, due to differences in outcomes evaluated, definitions of specific outcomes, as well as the n-3 FA intervention doses or compositions (for RCTs) or the dietary/biomarker n-3 FA exposure assessments and quantifications (for observational studies). Overall we found a lack of conclusive or consistent findings for CVD events within RCTs, mostly due to sparse data and underpowered trials as indicated by wide confidence intervals. The majority of the individual RCTs did not find statistically significant effects of marine oil supplements (EPA+DHA, various doses) on CVD outcomes. Pooled meta-analyses suggest that people with CVD or at risk for CVD who received marine oil supplements may have a small risk reduction in CVD death (pooled HR 0.92; 95\% CI 0.82 to 1.02) compared with those who received placebo. Across outcomes, the effects of marine oil supplements were often larger in earlier RCTs than in more recent RCTs. These data may be confounded by shifts over time in concomitant therapy to reduce CVD risk (e.g., statins, aspirin), decreasing smoking rates, and overall declining rates of CVD events. No meta-regression across studies found significant changes in effect sizes by publication year; however, it is likely that all such meta-regressions of clinical outcomes were underpowered due to relatively small numbers of trials.

Observational studies were mixed regarding the associations between n-3 FA intake or biomarkers and risk of MACE (where each study used its own combination of specific CVD outcomes). The strength of associations between higher levels of n-3 FA and lower risk of CVD outcomes, when found, were often larger than those in RCTs. While all observational studies adjusted associations for potentially confounding variables, the specific variables included in models varied greatly across observational studies. Furthermore, all observational studies compared higher intake levels of n-3 FA with lowest intake level, which included people who may have other nutrition deficiencies that may affect chronic disease risks but often cannot be "controlled for" in the analyses (resulting in residual, uncontrolled confounding).

The overall findings for the effects of marine oil supplements on intermediate CVD outcomes remain largely unchanged since the original report. In this update, there were no significant effects found in 29 RCTs that compared marine oils ( $0.3-6 \mathrm{~g} / \mathrm{d}$ ) on systolic or diastolic BP compared with placebo. Thirty-three RCTs evaluated LDL-c and HDL-c. Metaanalyses of the effect of marine oils on HDL-c and LDL-c found small, but statistically significant amounts (summary net change HDL-c $=1.2 \mathrm{mg} / \mathrm{dL}$ [95\% CI 0.6 to 1.8]; LDL-c $=2.0$ $\mathrm{mg} / \mathrm{dL}$ [95\% CI 0.4 to 3.6]). The clinical significance of these small increases in both HDL-c and LDL-c on CVD outcomes, particularly in combination, is unclear. For both lipids, no differences in effect across studies were found by marine oil dose, followup duration or population. The strongest effect of marine oils ( $0.3-6 \mathrm{~g} / \mathrm{d}$ ) was found among the 40 RCTs of Tg. Meta-analysis found a summary net change of $-23 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-29$ to -18 ), with no significant difference in effect based on population or followup time across studies. However, across trials, the effect was dose-dependent and also dependent on the studies’ mean baseline Tg values. By metaregression, each increase of EPA+DHA dose by $1 \mathrm{~g} / \mathrm{d}$ was also associated with a greater net change Tg of $-6.8 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-11.4$ to -2.2 ) and each increase in mean baseline Tg level by $1 \mathrm{mg} / \mathrm{dL}$ was associated with a greater net change Tg of $-0.12 \mathrm{mg} / \mathrm{dL}(95 \% \mathrm{CI}-0.22$ to -0.03 ). However, the few trials that directly compared marine oil doses did not consistently find a dose effect; although, marine oil doses $\geq 3 \mathrm{~g} / \mathrm{d}$ all resulted in larger reductions in Tg compared to lower doses, in contrast to doses $<3 \mathrm{~g} / \mathrm{d}$ which had smaller reductions in Tg compared to even lower doses. There were no observational studies evaluating these intermediate CVD outcomes.

In the original report, there was only one RCT of ALA (linseed oil) versus control oil (sunflower seed oil), ${ }^{49}$ conducted in the 1960s, that evaluated clinical event outcomes. In this update we identified only one additional RCT of ALA (plant source not reported) versus placebo (oleic acid) in participants with a history of MI that reported clinical outcomes. ${ }^{119}$ Given the sparseness of trials of the effect on clinical CVD outcomes of higher ALA intake and the differences between the two trials, no conclusion can be drawn regarding effect of ALA on CVD outcomes. For intermediate outcomes, five ALA RCTs (with doses ranging from 1.4 to $5.9 \mathrm{~g} / \mathrm{d}$ ) evaluated BP outcomes, and four of the five RCTs also evaluated LDL-c, HDL-c, Tg, or Total:HDL-c ratio (2 trials) outcomes. All found no significant differences in these outcomes between ALA and placebo. Thirteen observational studies evaluated ALA intake. The large majority of analyses found no significant associations; only two studies found any significant associations between higher ALA intake and clinical outcomes (reduced all-cause death, SCD, and CHD death risks).

The potential threshold-effects of n-3 FA on CVD events could not be determined from the RCTs because there were limited number of RCTs for many outcomes and most RCTs did not find significant effects. Only for Tg is there evidence among trials of a dose effect, such that higher dose marine oils result in greater reductions in Tg. Using data from observational studies, the linear dose-response and potential threshold effects of n-3 FA on several CVD events were tested by meta-analytical techniques. There was a near-significant association between EPA and DHA intake and CHD across a median dose range of 0.04 to $3.47 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=0.90$ [95\% CI 0.80 to 1.01]), and a just-significant association between EPA and DHA intake and higher risk of ischemic stroke across a median dosage range of 0.025 to $0.6 \mathrm{~g} / \mathrm{d}$ (effect size per $\mathrm{g} / \mathrm{d}=1.03$ [ $95 \%$ CI 1.00 to 1.07]), but no dose-response relationships found between EPA and DHA intake and hemorrhagic stroke. The interpretations of the threshold-effects were limited because differences in associations at lower doses (statistically significant associations between higher intake and lower risk) and associations at higher doses (no significant associations between intake and outcome) were generally similar regardless of the cut point chosen between lower and higher dose analyses.

No differences in effects or associations were found between different populations (healthy or general population, at increased risk for CVD-largely due to dyslipidemia, or with CVD). However, this conclusion is weak given that few studies compared populations, few RCTs were conducted in healthy populations and few observational studies were conducted in at risk or CVD populations.

## Limitations

Overall, both RCTs and observational studies (i.e., longitudinal observational and nested case-control studies) included in this systematic review generally had few risk of bias concerns. Across RCTs, the most common risk of bias limitation was a lack of intention-to-treat analyses ( $25 \%$ of the included RCTs). Of included RCTs, 18 percent could not blind study participants because the intervention was dietary (increased fish intake, not n-3 FA supplements), and 15 percent of RCTs were at risk of attrition bias primarily due to overall dropout rates greater than 20 percent. Most studies reported similar dropout rates between groups. Although more than 90 percent of the included RCTs reported similar baseline demographic characteristics between groups, about 40 percent did not report baseline n-3 FA intake or status. This is a critical point because baseline n-3 FA status likely affects response to changes in n-3 FA intake (diet or supplements). Across observational studies, the most common risk of bias limitation was
reporting inadequacy related to the ranges and distribution of n-3 FA exposures (45\% did not fully report such data). Of included observational studies, 12 percent did not report the dietary assessment instrument, and most of the n-3 FA dietary intake assessment included only dietary sources (not n-3 FA supplements). At best, studies reported that they used a food frequency questionnaire to estimate n-3 FA intake, without complete details. Of those studies that reported biomarker data, this is not an issue of concern. However, a variety of different n-3 FA biomarkers were investigated across studies, making comparisons and meta-analysis difficult.

For clinical CVD outcomes, all but one of the RCTs was conducted in either high risk individuals or people with existing CVD. In contrast, most observational studies examining the associations between dietary n-3 FA intake or biomarkers of n-3 FA intake and clinical outcomes were conducted in generally healthy populations. The definitions of most clinical outcomes were heterogeneous across studies regardless of the study designs. For most clinical outcomes, there were few or no RCTs. Few trials compared n-3 FA dose, formulation, or source. No trial compared different n-3 to n-6 FA ratios of supplements or intake. None of the observational studies attempted to determine a threshold effect of any associations between n-3 FA and the outcome of interest.

Other study-reporting issues that precluded analyses from being included in metaanalyses were that studies of n-3 FA intake used a variety of methods to measure intake (g/d, percent Kcal, percent fat or fatty acid intake); several studies failed to report median or range data of n-3 FA levels within quantiles, confidence intervals (or equivalent) of association hazard ratios, or conducted only linear analyses across a full range of n-3 FA values. In addition, studies varied in the range of n-3 FA status (e.g., intake level) within each study, often with n-3 FA ranges that did not or hardly overlapped. All of the observational studies measured dietary n-3 FA intake or biomarkers of n-3 FA intake at a single time point, baseline, and related these data to the long-term (mostly >10 years) clinical outcomes (CVD events). These analyses rely on the assumption that baseline intake reflects long-term intake, both prior to the beginning of the study and during the course of the observational period. In adults, the relative stability of dietary patterns may minimize the bias due to changing dietary patterns. However, study participants may have changed their dietary or supplement intake of n-3 FA due to concerns about CVD, due to advancing age or new CVD risk factors (e.g., new diagnoses of hypertension, diabetes, or dyslipidemia). These potential dietary changes are unlikely to have occurred at random and may, therefore, introduce bias due to the differential misclassifications of exposure status. This review included neither weight-loss intervention studies nor did we evaluate weight change as an outcome. We also did not include post hoc subgroup analyses (with subgroups defined by status at study end; e.g., by weight loss). Very few, if any, eligible studies evaluated weight change or its interaction with CV-related outcomes. Therefore, this review cannot comment on any potential interactions between weight change and n-3 FA status on CV outcomes.

There are numerous differences between RCTs and observational studies, making the comparisons across the two study designs difficult to make. Of note, the doses of marine oil supplements (EPA+DHA) in RCTs were often much higher than the highest intake reported for observational studies. Furthermore, not all observational studies explicitly included n-3 FA supplements in their assessment of intake and very few of the RCTs attempted to account for background fish or n-3 FA intake as an effect modifier.

Due to significant clinical heterogeneity across studies, the interpretation of overall metaanalysis results is limited. Dose-response meta-analysis of observational studies should be
interpreted with caution as many factors many invalidate the results such as heterogeneity in the covariate adjustments across studies and errors or biases in dietary assessments.

While this report represents a complete systematic review, it does not encompass all trials or longitudinal observational studies that report on CVD and intermediate outcomes. Particularly, if one includes small studies (trials with <30 participants per study group or observational studies with <100 participants, several hundred more studies could potentially have met eligibility criteria. Due to time and resource limitations, we restricted the review to the approximately 100 studies that are most likely to have adequately addressed the primary research questions of interest.

## Future Research Recommendations

Future RCTs should characterize the preparations of n-3 FA and placebo used for the intervention in terms of the FA composition and molecular form of the FA (e.g., ethyl esters, Tg ), as well as indicating their sources. Of potential interest in future studies is whether effects differ based on these factors. The placebo foods and oils should have the same caloric density and to the extent possible similar food or oil types as the source of n-3 FA. The composition of the background diet should also be reported, as should FA composition, macronutrient content and whether the participants were weight-stable. Researchers are encouraged to use standard, common CVD outcomes to allow comparison across studies. Assessment of n-3 FA status and intake should be evaluated at study entry and post-intervention in all study participants using to better understand potential changes in n-3 FA intake in populations with different background diets (e.g., whether the effect of supplementation differs in people with high- or low-fish diets). If trials include participants with a broad range of n-3 FA status or intake (e.g., with both highand low-fish diets), subgroup analyses should be conducted to evaluate possible differential effects based on these variables. The effects (or lack thereof) of marine oils (EPA+DHA) on BP, LDL-c, HDL-c, and Tg are well established so additional RCTs on these intermediate outcomes alone are unlikely to add any new knowledge, and therefore are not recommended.

There is an ongoing need to improve self-reported dietary assessment methods and food databases for all nutrients including n-3 FA. As national dietary patterns shift and new processed foods are introduced into the marketplace, food composition tables used to analyze food frequency questionnaire data need to be updated to ensure accurate estimation of n-3 FA (and other nutrient) intake. Similar to trial registries, a data repository for raw observational study data would greatly improve the transparency of data analyses (potentially reduce both reporting and publication biases) and the appropriateness and methodology of meta-analytical techniques for pooling observational studies. An individual participant-level meta-analysis of observational studies of marine oils could address limitations of the study-level meta-analyses that are currently feasible.

## Conclusions

Results from the RCTs of clinical event outcomes are applicable only to at risk of CVD and CVD populations. Results from the RCTs of intermediate outcomes are applicable to all populations. In contrast, results from observational studies (which did not evaluate intermediate outcomes) are applicable only to generally healthy populations. We graded the strength of the body of evidence for each intervention/exposure and comparison of intervention, and for each outcome by assessing the number of studies, their study designs, the study limitations (i.e., risk of bias and overall methodological quality), the directness of the evidence to the Key Questions,
the consistency of study results, the precision of any estimates of effect, the likelihood of reporting bias, and the overall findings across studies. We concluded that there is insufficient evidence regarding the effect of or association between total n-3 FA (ALA + marine oils $[E P A+D H A+D P A)$ and clinical or intermediate outcomes. There is low strength of evidence of no association between total n-3 FA intake and stroke death, and total (fatal and nonfatal) MI (each association based on longitudinal observational studies). For marine oil (EPA + DHA $\pm$ DPA), there is insufficient evidence for most outcomes of interest but there is low to high strength of evidence of a beneficial effect of higher marine oil intake for selected CVD and intermediate outcomes. Specifically, there is high strength of evidence of that marine oils clinically and statistically significantly lower Tg-possibly with greater effects with higher doses and in people with higher baseline Tg . There is also high strength of evidence that marine oils statistically, but arguably not clinically, significantly raise both HDL-c and LDL-c. There is also high strength of evidence that marine oil significantly lowers Total:HDL-c ratio. There is low strength of evidence that marine oil supplementation lowers risk of ischemic stroke. There is a high strength of evidence of no effect of marine oil on risk of MACE, all-cause death, sudden cardiac death, coronary revascularization, and blood pressure; moderate strength of evidence of no effect of marine oil on risk of atrial fibrillation; and low strength of evidence of no associations of marine oil intake and cardiovascular death, CHD death, CHD, myocardial infarction, angina pectoris, CHF, total stroke, or hemorrhagic stroke.

For individual n-3 FA, there is insufficient evidence regarding the effect of or association with EPA, DHA, DPA, stearidonic acid (SDA), or ALA (specifically) and most CVD clinical outcomes. For EPA, there is low strength of evidence of no association between EPA intake and CHD and between EPA biomarkers and AFib. For DHA, there is moderate strength of evidence of no effect of purified DHA supplementation on BP or LDL-c and low strength of evidence of no association between DHA intake and incident CHD (from observational studies). For DPA, there is low strength of evidence of an association between higher DPA biomarker levels and lower risk of AFib. For ALA, there is moderate strength of evidence of no significant effect of ALA intake on BP, LDL-c, HDL-c, or Tg. There is low strength of evidence of no association between ALA intake or biomarker level and CHD or CHD death, AFib, or CHF, based on observational studies.

There is insufficient evidence of direct comparisons between marine oil and ALA intake on CVD outcomes. Across studies, the comparison between marine oil and ALA is unclear, largely because of insufficient evidence regarding ALA; however, where there is high strength of evidence of significant effects of marine oil on improving Tg and HDL-c, there is moderate strength of evidence of no effect of ALA intake on these intermediate outcomes. No RCTs examined the additive effects of n-3 FA versus the effects of individual n-3 FA.

In the scientific community, there is a perception of "conflicting evidence" for the role of n-3 FA in prevention or treatment of CVD between RCT and observational study data. ${ }^{196,197}$ This perception may in part stem from inconsistent scientific conclusions among several of the expert panels or may relate to whether the potential beneficial effects of n-3 FA were from fish (or other marine foods) intake or from dietary supplements. ${ }^{5-8}$ Our qualitative comparisons between RCTs and observational studies (i.e., longitudinal observational and nested case-control studies) included in this systematic review showed that the evidence base from the two study designs relating n-3 FA to CVD outcomes often are not comparable as they address different
research questions. It is important to note that observational studies of fish consumption without quantifications of n-3 FA were not included in this systematic review. Our findings highlight the importance of including both observational studies and RCTs to assess the strength of body of evidence because the two study designs each have their own strengths and weakness and often provide complementary pieces of information for causal inferences. Nutrition observational studies typically measure and compare people with different dietary behaviors (thus different levels of nutrient exposure) in relationship to the disease risks, while nutrition RCTs are typically designed to compare a specific (usually narrowly defined) nutrition intervention to a control) in a relatively homogenous and well-defined study population. By design, nutrition observational studies and RCTs address different research questions. The observed relationships between higher or lower levels of intake and disease risks are important to describe potential behavioral target for interventions for prevention or treatment of a disease but will never be sufficient to pin point the specific mechanism or doses for the interventions. Therefore it is unlikely that a RCT can be designed to "verify" or "validate" nutrition observational results. On the other hand, RCTs are the most valid design for comparative effectiveness research questions. Long-term nutrition RCTs, however, often suffer compliance or contamination issues that can void the advantages of initial randomization. No single study can provide a "definitive answer" due to the unique challenges in nutrition RCTs and observational studies. It is necessary to carefully review the totality of evidence while considering the strengths and limitations of the individual studies.

## Appendix E. Study Design

Table E-1. Comparative studies

| Author, year, PMID, country, trial name | Study Design, study start date | Funding source/Conflict of interest | Duration of Intervention/ duration of washout period | Eligibility Criteria | Study Population |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Baxheinrich, 2012, 22894911, Germany | Trial: Randomized Parallel, 2010 (approx.) | Industry funded/No conflict of interest (explicitly stated) | 6 months | To be enrolled in the study, subjects had to meet the diagnosis criteria of the metabolic syndrome according to the definition of the International Diabetes Federation (Table 1). Exclusion criteria were CVD, severe illnesses such as renal failure or liver disease, food allergy or intolerance, pregnancy or lactation, smoking, alcohol abuse and insulin therapy or severe diabetic complications in case of diagnosed type 2 diabetes mellitus. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Diabetes and/or metabolic syndrome* |

| Author, year, PMID, country, trial name | Study Design, study start date | Funding source/Conflict of interest | Duration of Intervention/ duration of washout period | Eligibility Criteria | Study Population |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Bosch, 2012, 22686415, Canada, ORIGIN | Trial: Randomized Factorial Design, 2003 | Industry funded | 2 years | At least 50 years old; a diagnosis of diabetes with receipt of no more than one oral glucose-lowering drug, impaired glucose tolerance (plasma glucose level at 2 hours, $=7.8 \mathrm{mM}[140$ mg per deciliter] and <11.1 mM [200 mg per deciliter] after a $75-\mathrm{g}$ oral glucose load), or impaired fasting glucose (range, $=6.1 \mathrm{mM}[110 \mathrm{mg}$ per deciliter] to $<7.0 \mathrm{mM}$ [ 126 mg per deciliter]); a history of myocardial infarction, stroke, or revascularization; angina with documented ischemia; a ratio of urinary albumin to creatinine of more than 30 mg per gram; left ventricular hypertrophy; $50 \%$ or more stenosis of a coronary, carotid, or lower-limb artery on angiography; or an ankle brachial index of less than 0.9 . Participants were excluded if they were unwilling to discontinue use of a nonstudy preparation of n 3 fatty acids, had a locally measured glycated hemoglobin level of $9 \%$ or more, had undergone coronary-artery bypass grafting within the previous 4 years with no intervening cardiovascular event, had severe heart failure, or had a cancer that might affect survival. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Diabetes and/or metabolic syndrome*; Hypertension; Cardiac disease; Cerebrovascular disease; Peripheral vascular disease; Arrhythmia |

| Author, year, PMID, country, trial name | Study Design, study start date | Funding source/Conflict of interest | Duration of Intervention/ duration of washout period | Eligibility Criteria | Study Population |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Brinton, 2013, 23835245, US, ANCHOR | Trial: Randomized Parallel | Industry funded | 12 weeks | >18 years of age at high risk for CVD (patients with clinical coronary heart disease [CHD] or CHD risk equivalents [10-year risk 20\%]) as defined by the National Cholesterol Education Program Adult Treatment Panel III (NCEP-ATP III) guidelines. On stable statin therapy (atorvastatin, rosuvastatin, or simvastatin with or without ezetimibe) for 4 weeks at doses expected to produce "optimal" LDLC levels for high-risk patients ( 40 and $<100 \mathrm{mg} / \mathrm{dL}$ ). Patients who had A1c $>9.5 \%$ or were being treated with antidiabetes medication that had not been stable for 4 weeks at screening were excluded from the ANCHOR study. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease) |
| Brouwer, 2006, 16772624, Germany, Netherlands, Sweden, UK, Poland, Czech Republic, Belgium, Austria, SOFA trial | Trial: Randomized Parallel, 2001 | No industry relationship reported (funding or affiliations reported)/No Data regarding conflict of interest | 12 months | Men and women >=18 years old, experienced at least 1 true, confirmed, spontaneous VT or VF in the preceding year, and either had and ICD or were about to receive one. Exclusion: receipt of an ICD for prophylactic reasons; ICD as a "bridge" to heart transplantation; refractory supraventricular arrhythmia with rapid ventricular rates despite antiarrhythmic therapy; a projected life span of <1 year; use of supplemental omega-3 PUFA during the past 3 months or consumption $>8 \mathrm{~g}$ of omega3 PUFAs from fish or seafood per month ( $267 \mathrm{mg} / \mathrm{d}$ ) as judged by a seafood FFQ; pregnant women; women of childbearing age who did not use adequate contraception, and patients with a known history of recent drug or alcohol abuse.. excluded patients with high baseline omega-3 intake from supplements and/or foods | Secondary Prevention (history of CVD event): Arrhythmia (at least 1 true, confirmed, spontaneous VT or VF in the preceding year, and either had and ICD or were about to receive one.) |

| Author, year, PMID, country, trial name | Study Design, study start date | Funding source/Conflict of interest | Duration of Intervention/ duration of washout period | Eligibility Criteria | Study Population |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Caslake, 2008, 18779276, UK, FINGEN | Trial: Randomized Crossover, 2003 | Industry funded/Conflict of interest stated (CMW is a consultant to Pepsico UK and Unilever PIc. PCC is a consultant to Equazen, Royal Dutch Numico, and Mead Johnson Nutritionals and accepts speaking fees from Solvay Healthcare, Solvay Pharmaceuticals, B Braun Melsungen, and Fresenius Kabi. None of the other authors had a personal or financial conflict of interest.) | three 8-weeks intervention period separated by two 12-weeks washout periods/12 weeks | The volunteers were generally fit and healthy. Exclusion criteria for participation in the study were diagnosed diabetes or fasting glucose concentrations of $>6.5 \mathrm{mmol} / \mathrm{L}$; liver or other endocrine dysfunction; a myocardial infarction in the previous 2 $y$; hypolipidemic therapy or any other medication known to interfere with lipid metabolism; consumption of FA supplements or oily fish $>1$ time/wk; current use of a weight-reducing diet; body mass index (in kg/m2) of <18.5 or $>30$; or fasting total cholesterol (TC) and TAG concentrations of $>8.0$ and $3.0 \mathrm{mmol} / \mathrm{L}$, respectively. | Primary Prevention, Healthy |
| Damsgaard, 2008, 18492834, Denmark | Trial: Randomized Factorial Design, 2005 | Industry only donated materials (eg, supplements)/No conflict of interest (explicitly stated) | 8 weeks | Healthy males, aged $18-40 \mathrm{y}$, with no chronic diseases, no regular medication, and no strong allergies who were smoking < 5 cigarettes/week, exercising strenuously $<7 \mathrm{~h} / w k$, eating homemade meals $>5 \mathrm{~d} / \mathrm{wk}$, and consumed butter/margarine/or oil daily. | Primary Prevention, Healthy |

| Author, year, PMID, country, trial name | Study Design, study start date | Funding source/Conflict of interest | Duration of Intervention/ duration of washout period | Eligibility Criteria | Study Population |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Derosa, 2009, 19397392, Italy | Trial: Randomized Parallel | Industry only donated materials (eg, <br> supplements)/No conflict of interest (explicitly stated) | 6 months | Caucasian patients aged 18 years of either sex were eligible for inclusion in the study if they had combined dyslipidemia (defined by the International Lipid Information Bureau), identified by total cholesterol (TC) > $200 \mathrm{mg} / \mathrm{dl}$ and triglycerides $(\mathrm{Tg})>200$ $\mathrm{mg} / \mathrm{dl}$, and who had never previously taken lipid-lowering medications. Patients were excluded if they had a genetic condition affecting lipid metabolism (e.g., familial hypercholesterolemia, type III hyperlipidemia, LPL deficiency, etc.); a history of microalbuminuria or nephrotic syndrome; an impaired hepatic function (defined as plasma aminotransferase and/or glutamyltransferase level higher than the upper limit of normal for age and sex); an impaired renal function (defined as serum creatinine level higher than the upper limit of normal for age and sex); thyroid diseases; endocrine or metabolic disease; a history of alcohol or drug abuse; a neoplastic, infectious or autoimmune disease; poor mental condition or if they were taking any other drug that was able to influence lipid metabolism. Patients with serious cardiovascular disease (e.g., New York Heart Association class I IV congestive heart failure or a history of myocardial infarction or stroke) or cerebrovascular conditions in 6 months before study enrollment were also excluded. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Dyslipidemia (total cholesterol (TC) > 200 $\mathrm{mg} / \mathrm{dl}$ and triglycerides $(\mathrm{Tg})>200 \mathrm{mg} / \mathrm{dl})$ |

| Author, year, PMID, country, trial name | Study Design, study start date | Funding source/Conflict of interest | Duration of Intervention/ duration of washout period | Eligibility Criteria | Study Population |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Earnest, 2012, 22811376, US | Trial: Randomized Parallel, 2009 (approx.) | No Data on funding or affiliations | 12 weeks | Inclusion criteria for this study necessitated that participants have a HCY concentration $>8.0 \mathrm{mmol} / \mathrm{L}$. We excluded pregnant or lactating women from participation. Postmenopausal women both on and off hormone replacement therapy were accepted into the trial. We asked those on hormone replacement therapy to remain on their current medication and dosage schedule and notify us if the regimen was changed. Participants currently on standard medical therapy (for conditions such as hypertension, hypercholesterolemia, diabetes, arthritis, or other chronic diseases) were allowed to enter the study if they had been taking any medications for at least 6 months and agreed to remain on their current therapy during the trial. | Primary Prevention, Healthy; Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Diabetes and/or metabolic syndrome*; Hypertension; Dyslipidemia |
| Ebrahimi, 2009, 19593941, Iran | Trial: Randomized Parallel, 2007 (approx.) | No industry relationship reported (funding or affiliations reported) | 6 months | People with metabolic syndrome but who had not previously taken n-3 fatty acid capsules or other nutritional supplements. People who were $<40$ or $>70$ years old were excluded from the study. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Diabetes and/or metabolic syndrome* |

| Author, year, PMID, country, trial name | Study Design, study start date | Funding source/Conflict of interest | Duration of Intervention/ duration of washout period | Eligibility Criteria | Study Population |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Einvik, 2010, 20389249, Norway, DOIT | Trial: Randomized Factorial Design, 1997 | No industry relationship reported (funding or affiliations reported)/No Data regarding conflict of interest | 3 years | The basis for recruitment in the DOIT was the 910 survivors from a population of 1232 healthy men with hypercholesterolemia (> $6.45 \mathrm{mmol} / \mathrm{l}$ ) participating in the Oslo Diet and Antismoking Study, carried out from 1972 to 1977. Exclusion factors in the DOIT were: total cholesterol greater than $8 \mathrm{mmol} / \mathrm{I}$, blood pressure levels greater than $170 / 100 \mathrm{mmHg}$, specific disease states or practical causes thought to influence longevity, or compliance (cancer, end-stage renal failure, chronic alcoholism or travel distance $>200 \mathrm{~km}$ ). A total of 82 individuals were excluded and 10 individuals were unwilling to participate. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): <br> Dyslipidemia (hypercholesterolemia (> $6.45 \mathrm{mmol} / \mathrm{I})$ |
| Eritsland, 1996, 8540453, Norway, SHOT | Trial: Randomized Factorial Design, 1989 | Industry funded/No Data regarding conflict of interest | 1 year | Consecutive patients admitted for coronary artery bypass grafting without concomitant cardiac surgery, such as valve implantation or aneurysmectomy. Exclusion criteria: medical contraindications to any of the treatment principles ( $n=109$ ), refused participation ( $n=57$ ), early ( $\sim 2$ days) perioperative death $(n=13)$ or complications ( $n=32$ ), presumed lack of compliance ( $n=29$ ), indication for anticoagulation ( $n=27$ ), and administrative reasons ( $n=38$ ). | Secondary Prevention (history of CVD event): Cardiac disease (coronary artery bypass grafting without concomitant cardiac surgery) |

| Author, year, PMID, country, trial name | Study Design, study start date | Funding source/Conflict of interest | Duration of Intervention/ duration of washout period | Eligibility Criteria | Study Population |

| Finnegan, 2003, 12663273, UK | Trial: Randomized Parallel, 1998 | Industry funded/No Data regarding conflict of interest | 6 months | Moderately hyperlipidemic but otherwise healthy adults aged 25-72 y. Exclusion criteria for participation in the study were evidence of cardiovascular disease, including angina; diagnosed diabetes or a fasting glucose concentration > 6.5 $\mathrm{mmol} / \mathrm{L}$; liver or other endocrine dysfunction; pregnancy or lactation; smoking > 15 cigarettes/d; exercising strenuously > 3 times/wk; body mass index (in kg/m2) < 20 or > 32; and a hemoglobin concentration < $130 \mathrm{~g} / \mathrm{L}$ in men or $120 \mathrm{~g} / \mathrm{L}$ in women. Individuals who were prescribed hypolipidemic or antiinflammatory medication, took fatty acid or antioxidant supplements regularly, or consumed $>2$ portions of oily fish/wk were excluded. <br> Vegetarians and nonconsumers of margarine were also excluded. Moderate hyperlipidemia was defined as a fasting total cholesterol concentration between 4.6 and 8.0 $\mathrm{mmol} / \mathrm{L}$ and a triacylglycerol concentration between 0.8 and 3.2 $\mathrm{mmol} / \mathrm{L}$. | Primary Prevention, Healthy: Dyslipidemia |
| Galan, 2010, 21115589, France, SU.FOL.OM3 | Trial: Randomized Parallel, 2003 | Industry funded | $\begin{aligned} & \hline \text { Median } 4.7 \text { years } \\ & \text { (mean 4.2, SD 1.0) } \end{aligned}$ | History of CVD (acute coronary event, including ACS, or cerebral ischemic event, excluding TIA, within 12 mo ), $45-80 \mathrm{y}$. Exclude disease or treatment that might interfere with metabolism of homocysteine or n-3 FA (eg, methotrexate), $\mathrm{SCr}>200 \mathrm{mcmol} / \mathrm{L}$, $\mathrm{CrCl}<40 \mathrm{ml} / \mathrm{min}$. | Secondary Prevention (history of CVD event): Cardiac disease (Coronary event w/in 12 mo , including $\mathrm{MI}, \mathrm{ACS}$ or suspected ACS); Cerebrovascular disease (CVA (not TIA)) |

| Grieger, 2014, 24454276, Australia | Trial: Randomized Parallel, 2011 | Industry funded/No conflict of interest (explicitly stated) | 8 weeks | Community dwelling men and women >= 64 years of age, Inclusion criteria were: $\mathrm{BMI}>=18.5 \mathrm{~kg} / \mathrm{m} 2$ usual consumption of $<=1$ serving of fish/seafood per week, willing to consume eight servings of fish or red meat per fortnight. Exclusion criteria were: allergies to fish/seafood, vegetarian, intake of lipid-lowering medications; intake of lipid-lowering supplements (e.g. psyllium, fish oil capsules, soy lecithin, phytoestrogens or to cease 3 weeks prior to study commencement), use of antiinflammatory medications on a regular basis or if experiencing an acute episode within 1 week of the screening visit, presence of diabetes, liver, kidney, thyroid diseases (unless controlled and stable on replacement medication), presence of other endocrine disorders from self-reported medical history, weight loss or gain of $10 \%$ body weight in the prior 6 months, or clinically diagnosed depression or dementia.. | Primary Prevention, Healthy |
| Grimsgaard, 1998, 9665096, Norway | Trial: Randomized Parallel, 1993 | No Data on funding or affiliations/No Data regarding conflict of interest | 2 months | They reported being healthy nonsmokers, did not use nonprescribed or prescribed drugs, and consumed less than four fish dishes per week in their usual diet. They also had serum cholesterol concentrations $<8.0 \mathrm{mmo} / \mathrm{L}$, diastolic blood pressure < 95 mm Hg , and systolic blood pressure $<160 \mathrm{~mm} \mathrm{Hg}$. | Primary Prevention, Healthy |

| $\begin{aligned} & \text { Harrison, 2004, 15853118, } \\ & \text { UK } \end{aligned}$ | Trial: Randomized Factorial Design, 2001 | Industry only donated materials (eg, supplements) | 5 weeks | Men and women aged 45-59 with a total serum cholesterol $>=5.7 \mathrm{mmol} / \mathrm{I}$ or a mean SBP >= 130 mmHg or both. Exclusions: Those taking existing medications for blood pressure or cholesterol. Participants randomly selected from 12 general practices on the Islands of Lewis and Harris, whose inhabitants have high cholesterol. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Hypertension (SBP >= 130 mmHg ); Dyslipidemia (Total cholesterol >= 5.7 mmol/l) |
| Holman, 2009, 19002433, UK, AFORRD | Trial: Randomized Factorial Design, 2004 | Industry funded | 4 months | Patients with type 2 diabetes for at least 3 months, aged 18 years, with no known CVD events, and not thought by their general practitioner to be at high enough CVD risk to require immediate lipid-lowering therapy. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Diabetes and/or metabolic syndrome* |

| Author, year, PMID, country, trial name | Study Design, study start date | Funding source/Conflict of interest | Duration of Intervention/ duration of washout period | Eligibility Criteria | Study Population |

| Jones, 2014, 24829493, Canada, COMIT | Trial: Randomized Crossover, 2010 | Industry funded/Conflict of interest stated (All authors report having received grants and funding from food companies) | 4 weeks/4 weeks | Inclusion: any of the following: triglyceride level (TG) $1.7 \mathrm{mmol} / \mathrm{L}$, high density lipoprotein cholesterol level (HDL) $<1 \mathrm{mmol} / \mathrm{L}$ (males) or $<1.3$ mmol/L (females), blood pressure 130 mmHg (systolic) and/or 85 mmHg (diastolic) and glucose level 5.5 $\mathrm{mmol} / \mathrm{L}$, waist circumference 94 cm for men and 80 cm for women. Exclusion: thyroid disease (unless controlled by medication), diabetes mellitus, kidney disease, liver disease, current smokers, or those consuming more than two alcoholic drinks per week, or medications known to affect lipid metabolism or endothelial function (including aspirin or other non-steroidal anti-inflammatory drugs), cholestyramine, colestipol, niacin, clofibrate, gemfibrozil, probucol, or 3-hydroxy-3-methyl-glutaryl-CoA (HMGCoA) reductase inhibitors.. At the beginning of the study, the Adult Treatment Panel III (ATP III) metabolic syndrome criteria for waist circumference ( $>102 \mathrm{~cm}$ for men and $>88 \mathrm{~cm}$ for women) were followed [28]. As the trial progressed, the International Diabetes Federation (IDF) metabolic syndrome criteria for waist circumference ( 94 cm for men and 80 cm for women) were adopted to identify individuals in the initial stages of abdominal obesity who might benefit from dietary intervention. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Hypertension (blood pressure 130 mmHg (systolic) and/or 85 mmHg (diastolic)); Dyslipidemia (TG $1.7 \mathrm{mmol} / \mathrm{L}, \mathrm{HDL}<1$ $\mathrm{mmol} / \mathrm{L}$ (males) or <1.3 $\mathrm{mmol} / \mathrm{L}$ (females)); Obesity/Overweight (waist circumference 94 cm for men and 80 cm for women); Other (glucose level $5.5 \mathrm{mmol} / \mathrm{L}$ ) |

| Kastelein, 2014, 24528690, US, Denmark, Netherlands, India, Hungary, Ukraine, Russia, EVOLVE | Trial: Randomized Parallel, 2011 | Industry <br> funded/Conflict of interest stated (The authors <br> acknowledge that they have either received research grant funding from, or are employees of, or have ownership in Omthera <br> Pharmaceuticals, Inc, the manufacturer of the product studied. The relationship of authors Dr Kastelein, Mr Machielse, Mr Kling, and Dr <br> Davidson to <br> Omthera are considered significant according to the definitions used by the Food and Drug Administration. The following authors further disclose that they have other modest relationships with industry that might pose a potential conflict of interest(s): Dr Kastelein (Amarin), Dr Maki (Abbott, Amarin, DSM, GSK, Pharmavite, Trygg Pharma), Dr <br> Susekov (Abbott, Actavis, Amarin, Amgen, <br> AstraZeneca, Gedeon-Richter, Genzyme, KRKA, Merck, Novartis, Pfizer, Promed, | 12 weeks | Participants included men and women (nonpregnant, nonlactating) >=18 years of age with average serum TG concentrations >=500 mg/dL but <2000 mg/dL at screening (1 and 2 weeks before random assignment) who were either untreated for dyslipidemia or were using a stable (for at least 6 weeks before the first qualifying lipid measurement) dosage of a statin, CAI, or their combination. Subjects were also required to have a body mass index (calculated as weight divided by height squared; $\mathrm{kg} / \mathrm{m} 2$ ) $>=20$ and be willing to maintain their customary activity level, follow the TLC diet with weight maintenance, and restrict their consumption of fish to no more than twice per week throughout the study. Persons with known lipoprotein lipase impairment or deficiency, apolipoprotein (Apo) CII deficiency, or familial dysbetalipoproteinemia were excluded from the study, as were persons with a history of pancreatitis, symptomatic gallstone disease (unless treated with cholecystectomy), uncontrolled diabetes (glycosylated hemoglobin $\$ 9 \%)$, or cancer in the past 2 years (basal cell carcinoma was not exclusionary). Persons with a recent history (past 6 months) of a cardiovascular event (ie, myocardial infarction, acute coronary syndrome, new onset angina, stroke, transient ischemic attack, or unstable congestive heart failure that required a change in treatment); revascularization procedure; aortic aneurysm; nephrotic syndrome; or pulmonary, hepatic, biliary, gastrointestinal, or immunologic disease were also excluded. Persons with uncontrolled hypothyroidism, thyroid-stimulating hormone $>5 \mathrm{mIU} / \mathrm{L}$, or poorly controlled hypertension (resting blood pressure >=160 mm Hg systolic or $>=100 \mathrm{~mm} \mathrm{Hg}$ diastolic) at 2 | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Dyslipidemia (average serum TG concentrations $500-2000 \mathrm{mg} / \mathrm{dL}$ ); Obesity/Overweight (body mass index $>=20$ ) |

| Kromhout, 2010, 20929341, Netherlands, DART | Trial: Randomized Factorial Design, 2002 | Industry only donated materials (eg, supplements)/No conflict of interest (explicitly stated) | 40 months | Men and women 60 to 80 years of age, who had had a clinical diagnosed MI up to 10 years before randomization. Exclusion criteria: daily consumption of $<1010 \mathrm{~g}$ of margarine, use of n -3 fattyacid supplements, unintended weight loss of $>5 \mathrm{~kg}$ in the previous year, and a diagnosis of cancer with an estimated life expectancy of $<1$ year. | Secondary Prevention (history of CVD event): Cardiac disease (myocardial infarction) |
| Kuhnt 2014, 24553695, Germany | Trial: Randomized Parallel, 2011 | No conflict of interest (explicitly stated) | 8 weeks | Normolipidemic and normal-weight (BMI 18-25) individuals were recruited for 2 age groups: group I, 20-35 y ; and group II 49-69 y. Older overweight individuals were recruited for echium oil (EO) intervention only (49-69 y; BMI $>25$ with markers of metabolic syndrome or $\mathrm{BMI}>=30$ ). Patients with markers of metabolic syndrome were mainly enlisted from the diabetes research center. This subgroup - EO III (older overweight individuals who were recruited for echium oil intervention only; 49-69 y; BMI >25 with markers of metabolic syndrome) was not included in this systematic review. | Primary Prevention, Healthy |
| Leaf, 2005, 16267249, US | Trial: Randomized Parallel, 1999 | Industry only donated materials (eg, <br> supplements)/No Data regarding conflict of interest | 1 year | Subjects were included who had an ICD implanted because of a history of cardiac arrest, sustained ventricular tachycardia (VT), or syncope with inducible, sustained VT or ventricular fibrillation (VF) during electrophysiologic studies. The qualifying ICD implantation was required to have occurred within 12 months before entry into the study or if the patient had experienced at least 1 spontaneous ICD event for VT/VF in the preceding 12 months.. - | Secondary Prevention (history of CVD event): Arrhythmia (ICD implanted) |

| Liu, 2003, no PMID, Sweden | Trial: Randomized Parallel, 2001 (approx.) | No Data on funding or affiliations | 12 weeks | Patients with hyperlipidemia, fasting TC>6.2 mmol/L and/or fasting TG>1.8 $\mathrm{mmol} / \mathrm{L}$, were studied. The subjects had their first diagnosis of hyperlipidemia. Subjects with previously known lipid changes undergoing treatment were excluded, as well as subjects with allergy to statins, or with diabetes mellitus, liver, or renal disease, or other diseases that might influence lipid metabolism, and pregnant women. Participation in another drug study during the last month, and treatment with antimycotic drugs or antibiotics that might interfere with the effects of statins, or with other drugs that may influence lipid metabolism, were further reasons for exclusion. Patients with cancer or other serious diseases were also excluded. Subjects with obesity, high BMI, high blood pressure or insulin resistance were not excluded. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Dyslipidemia (fasting TC>6.2 mmol/L and/or fasting $\mathrm{TG}>1.8 \mathrm{mmol} / \mathrm{L}$ ) |
| Lungershausen, 1994, 7852747, Australia | Trial: Randomized Crossover, 1992 (approx.) | Industry only donated materials (eg, supplements) | 6 weeks/4-6 weeks | Volunteers with uncomplicated essential hypertension controlled by monotherapy with a beta-blocker or diuretic, or a combination of the two. Excluded if with history of unstable heart, renal, or liver disease, or with DBP $>105 \mathrm{mmHg}$, consumed more than 20 cigs or 40 g EtOH per day, or exercised erratically. Any variation in antihypertensive drug therapy would necessitate withdrawal of the individual from the study. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Hypertension (Treated for hypertension, on medication) |

| Maki, 2010, 20451686, US, COMBOS | Trial: Randomized Parallel, 2005 | Industry funded | 8 weeks | Eligible patients were men or women between the ages of 18 and 79 years who had been receiving a stable dose of a statin for the control of LDL-C levels for $=>8$ weeks before screening and were judged to be in good health on the basis of a medical history, physical examination, electrocardiogram, and laboratory tests, including serum chemistry, hematology, and urinalysis. Major inclusion criteria included a mean fasting TG level >=200 and <500 $\mathrm{mg} / \mathrm{dL}$, and a mean LDL-C level below or within $10 \%$ of the patient's NCEP ATPIII goal. Major exclusion criteria included poorly controlled diabetes mellitus (glycosylated hemoglobin [ HbAlc ] $>8.0 \%$ at screening); history of a cardiovascular event, a revascularization procedure, or an aortic aneurysm or resection within 6 months of screening; history of pancreatitis; sensitivity to statins or omega-3 fatty acids; poorly controlled hypertension (resting blood pressure =>160 mm Hg systolic and/or =>100 mm Hg diastolic at 2 consecutive visits); serum creatinine level =>2.0 $\mathrm{mg} / \mathrm{dL}$; serum transaminase (aspartate aminotransferase IAST] or alanine aminotransferase [ALT]) >1.5 times the upper limit of normal (ULN) ( $45 \mathrm{U} / \mathrm{L}$ for ALT, $31 \mathrm{U} / \mathrm{L}$ for AST); or creatine kinase (CK) level >2 times the ULN. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): <br> Dyslipidemia (mean fasting TG level_>200 and $<500 \mathrm{mg} / \mathrm{dL}$, and a mean LDL-C level below or within $10 \%$ of the patient's NCEP ATP III goal.) |

| Shaikh, 2014, 25185754, Canada | Trial: Randomized Parallel | No Data on funding or affiliations/No Data regarding conflict of interest | 8 weeks | Male and female study subjects >=18 years of age, with one or more risk factor for CVD, were deemed eligible for study enrollment if their fasting whole blood OS levels were $6.1 \%$ by weight of total blood fatty acid levels, and their serum TG was between 1.02 and $5.65 \mathrm{mmol} / \mathrm{L}$. Subjects were excluded from the study if they refused to provide informed consent, had a known allergy to fish, were premenopausal women, were currently taking hormone replacement therapy (HR), lipid-altering medication or LC $n$ PUFA supplements, had a history of alcohol abuse, were medically ill, had a history of ventricular arrhythmia, bleeding or clotting disorder, liver or kidney disease, autoimmune disorder or suppressed immune systems, myopathy or rhabdomyolysis, seizure disorder, or had an implantable cardioverter defibrillator. Subjects on a stable statin medication for a minimum of three months were eligible to enroll. | Primary Prevention, Increased CVD Risk (Diabetes, Hypertension) |
| Shidfar, 2003, 12847992, Iran | Trial: Randomized Factorial Design, 2001 (approx.) | No industry relationship reported (funding or affiliations reported) | 10 weeks | Entry criteria included a serum total cholesterol and triglyceride > 200 $\mathrm{mg} / \mathrm{dl}$; body mass index <30; and no recent symptomatic diabetes, thyroid, liver, or renal disease. Patients taking sex hormones, diuretics, thyroid medications, corticosteroids, antihypertensives, vitamin C, oral contraceptive agents, and any medications that might interfere with the evaluation of results were excluded. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Dyslipidemia (serum total cholesterol and triglyceride $>200 \mathrm{mg} / \mathrm{dl})$ |

| :---: | :---: | :---: | :---: | :---: | :---: |
| Sirtori, 1997, 9174486, Italy | Trial: Randomized Parallel, 1995 (approx.) | Industry funded/No Data regarding conflict of interest | 6 month | The study protocol allowed the selection of patients of both sexes, males aged 45-75 y and females aged $55-80 \mathrm{y}$, with hyperlipoproteinemias type IIB or IV (23) associated with at least one additional risk factor: impaired glucose tolerance, NIDDM, or arterial hypertension. Patients with severe intercurrent ailments, kidney or renal disease, intestinal malabsorption, duodenal ulcer not responsive to therapy, obese individuals with a body mass index (in kg/m2) 30, as well as noncompliant or unreliable patients were excluded from the study. All patients with a history of vascular or nonvascular brain disease (including epilepsy and alcoholism), severe hyperlipidemia needing drug treatment, severe hypertension (DBP > 110 mm $\mathrm{Hg}, \mathrm{SBP}>180 \mathrm{~mm} \mathrm{Hg}$ under antihypertensive treatment), myocardial infarction in the preceding 3 mo , or unstable angina were excluded. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Diabetes and/or metabolic syndrome*; Hypertension (Patients treated with antihypertensive drugs or who on more than one occasion in the past year had had a systolic blood pressure (SBP) 160 mm Hg , a diastolic blood pressure (DBP) 95 mm Hg , or both, independent of drug treatment, were considered to have arterial hypertension.); <br> Dyslipidemia (Patients with significant and stable triacylglycerol elevations ( $>2.26 \mathrm{mmollL}$, or 200 $\mathrm{mg} / \mathrm{dL}$ ) were selected. These were defined as type IIB if serum total cholesterol was > 7.21 mmol/L ( $270 \mathrm{mg} / \mathrm{dL}$ ) and type IV if cholesterol was $7.21 \mathrm{mmol} / \mathrm{L}(270 \mathrm{mg} / \mathrm{dL})$. Patients with total cholesterol concentrations $>7.76 \mathrm{mmollL}(300 \mathrm{mg} / \mathrm{dL})$ with triacylglycerol concentrations 4.52 mmollL ( $400 \mathrm{mg} / \mathrm{dL}$ ) were excluded for ethical reasons.); Other (Impaired glucose tolerance) |

| Tatsuno, 2013, 24314359, Japan, ORL | Trial: Randomized Parallel, 2009 | Industry funded; <br> Authors report industry affiliation/Conflict of interest stated SUBVALUE(KK and JO are employees of Takeda <br> Pharmaceutical <br> Company; IT has acted as a consultant to Takeda, YS has acted as a consultant to Astellas and others) | 1 year | Outpatients, aged 20 to 74 years undergoing lifestyle modification for hypertriglyceridemia, fasting triglyceride level >=150 mg/dL and < $750 \mathrm{mg} / \mathrm{dL}$ at weeks 4 and 2 during the screening period and a variation in fasting low-density lipoprotein cholesterol (LDL-C) level between weeks 4 and 2 of $<25 \%$ from the highest value. All subjects were advised about lifestyle modifications (dietary or exercise or both) at all visits during the study. The main exclusion criteria were coronary artery disease, an aortic aneurysm, or significant hemorrhagic disease within 6 months before the study; pancreatitis; lipoprotein lipase deficiency, apolipoprotein C-II deficiency, and type III familial hyperlipidemia; Cushing syndrome, uremia, systemic lupus erythematosus, or serum dysproteinemia; type 1 or uncontrolled type 2 diabetes mellitus (hemoglobin A1c \$8\%); stage III hypertension; and hepatic impairment.. Use of concomitant medications that might affect the evaluation of efficacy was not permitted, such as fish oil supplements (including any other products, medications, or investigational drugs that contained EPA-E or DHA), insulin, androgens, estrogens, progesterones, and systemic steroids. Antihyperlipidemic drugs (with the exception of EPA-E) and antidiabetic drugs (except insulin) were allowed, provided they had been initiated at least 4 weeks before the study and the dose was not changed during the screening or treatment periods. | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): <br> Dyslipidemia (fasting triglyceride level >=150 $\mathrm{mg} / \mathrm{dL}$ and $<750 \mathrm{mg} / \mathrm{dL}$ at weeks 4 and 2 during the screening period) |

| Tavazzi, 2008, 18757090, Italy, GISSI-HF | Trial: Randomized Parallel, 2002 | Industry funded | 3.9 years | Eligible patients were men and women aged 18 years or older, with clinical evidence of heart failure of any cause that was classified according to the European Society of Cardiology (ESC) guidelines as New York Heart Association (NYHA) class II IV, provided that they had had their LVEF measured within 3 months before enrolment. When LVEF was greater than $40 \%$, the patient had to have been admitted at least once to hospital for heart failure in the preceding year to meet the inclusion criteria. Major exclusion criteria included specific indication or contraindication to $\mathrm{n}-3$ PUFA; known hypersensitivity to study treatments; presence of any noncardiac comorbidity (eg, cancer) that was unlikely to be compatible with a sufficiently long follow-up; treatment with any investigational agent within 1 month before randomisation; acute coronary syndrome or revascularisation procedure within the preceding 1 month; planned cardiac surgery, expected to be done within 3 months after randomisation; significant liver disease; and pregnant or lactating women or women of childbearing potential who were not adequately protected against becoming pregnant.. | Secondary Prevention (history of CVD event): Cardiac disease (symptomatic heart failure of any cause and with any level of left ventricular ejection fraction (LVEF).) |
| Tierney, 2011, 20938439, Netherlands, Norway, Sweden, UK, Ireland, France, Poland, Spain, LIPGENE | Trial: Randomized Parallel, 2004 | Authors report industry affiliation | 3 months | 3-5 characteristics of Metabolic Syndrome (see Comment about Eligibility Criteria). 1. fasting glucose conc $5.5-7 \mathrm{mmol} / \mathrm{I}$, 2. serum TAG $>1 / 5$ $\mathrm{mmol} / \mathrm{l}, 3$. serum HDL conc $<1.0$ $\mathrm{mmol} / \mathrm{L}$ (men) or $<1.3 \mathrm{mmol} / \mathrm{L}$ (women), 4. BP : systolic $>130 \mathrm{~mm} \mathrm{Hg}$, diastolic BP $>85 \mathrm{~mm}, 5$. Waist girth $>102 \mathrm{~cm}$ (men) or $>88 \mathrm{~cm}$ (women). | Primary Prevention, Increased CVD Risk (ie, diabetes, metabolic syndrome*, hypertension, dyslipidemia, or chronic kidney disease): Diabetes and/or metabolic syndrome* |

| $\begin{aligned} & \text { Koh, 2013, } \\ & \text { 24343844, China } \end{aligned}$ | The Singapore Chinese Health Study | Prospective, longitudinal study of intake (eg, FFQ, biomarker) | No industry relationship reported/No conflict of interest | 1993 | We excluded individuals who had baseline cancer ( $n=1936$ ) or reported extreme energy intakes (<600 or >3000 kcal/day for women and $<700$ or $>3700 \mathrm{kca} /$ /day for men; $\mathrm{n}=$ 1023). | Primary Prevention, Healthy |
| $\begin{aligned} & \hline \text { Larsson, 2012, } \\ & 22265275, \\ & \text { Sweden } \end{aligned}$ | Swedish <br> Mammography Study | Prospective, longitudinal study of intake (eg, FFQ, biomarker) | No industry relationship reported/No conflict of interest | 1997 | All women in the Swedish population register born between 1914 and 1948 and living in Vastmanland and Uppsala counties in central Sweden. Only women who completed the 1997 questionnaire are included in this study. Participants who did not provide or provided incorrect national identification numbers, who reported implausible energy intakes (>3 standard deviations from the natural logarithm transformed mean), who had a previous diagnosis of cancer (other than nonmelanoma skin cancer) or HF were excluded. Only women with no baseline history of MI or diabetes were included. | Primary Prevention, Healthy |

| $\begin{aligned} & \hline \text { Lemaitre, 2012, } \\ & \text { 22743310, US } \end{aligned}$ | Cardiovascular Health Study | Prospective, longitudinal study of intake (eg, FFQ, biomarker) | Authors report industry affiliation | 1989 | The cohort consisted of 5201 noninstitutionalized men and women aged $\$ 65$ y, recruited in 1989 1990, plus an additional 687 black participants recruited in 1992 and 1993. Each paper excluded participants with their outcome of interest at baseline. | Primary Prevention, Healthy |
| $\begin{aligned} & \hline \text { Levitan, 2009, } \\ & \text { 19383731, } \\ & \text { Sweden } \end{aligned}$ | Cohort of Swedish Men | Prospective, longitudinal study of intake (eg, FFQ, biomarker) | No industry relationship reported/No conflict of interest | 1997 | Men. Excluded based on previous diagnosis of cancer (except non-melanoma skin cancer), implausible energy intake (. 3 standard deviations from the natural logarithm transformed mean) $(n=562)$ or a history of HF at baseline ( $n=743$ ) were also excluded. In the primary analyses men with baseline history of MI ( $n=2077$ ) or diabetes ( $n=3157$ ) were excluded because they had higher rates of HF and may have changed their diets because of their diagnosis. | Primary Prevention, Healthy |
| Matsumoto, 2013, 23098619, US | Physician's Health Study (Also see Morris 7598116 entry) | Nested Case Control | No industry relationship reported/No conflict of interest | 1995-2001 | An ancillary study of PHS: randomly selected 1000 incident CHD cases that provided blood samples between 1995 and 2001. Density sampling technique to select 1 control who was alive and free of confirmed CHD at the time of the index case diagnosis and matched on age at blood collection (within 1 year), year of birth (within 2 years), and time of blood collection (within 3 months). | Primary Prevention, Healthy |
| Miyagawa, 2014, 24468152, <br> Japan | NIPPON-DATA | Prospective, longitudinal study of intake (eg, FFQ, biomarker) | Industry funded/No conflict of interest | 1980 | A total of 10,546 community residents free from CVDs at baseline(4639 men and 5907 women, aged 30 and greater) from 300 randomly selected districts from all-over Japan participated in the survey, with the participation rate of about 77\%. Accordingly, these participants were thought to be representative of the Japanese population. A total of 1356 men and women excluded from this analysis for the following reasons: history of CVD (n 350), missing information (e.g., nutrition, lifestyle questionnaire) at baseline (n $=124$ ), intake of energy more than 5000 kcal/day or less than $500 \mathrm{kcal} / \mathrm{day}$ ( n 139 ) and lost to follow-up due to incomplete residential addresses at the baseline survey ( $n=1104$ ). | Primary Prevention, Healthy |

| 328 | Women's Health Study | 25 |
| 329 | Women's Health Study | 25.5 |
|  |  |  |

## Causality Table: Observational Studies

| Row | Study | Baseline n-3 intake/level (median (IQR), unless noted) |
| :---: | :---: | :---: |
| 323 | Women's Health Initiative | ALA: $1.02 \mathrm{~g} / \mathrm{d}, \mathrm{DHA}+E P A: 0.093$ |
| 324 | Women's Health Initiative | ALA: $1.02 \mathrm{~g} / \mathrm{d}, \mathrm{DHA}+E P A: 0.093$ |
| 325 | Women's Health Study | All n-3 FA: $10.4 \mathrm{~g} / \mathrm{d}$ |
| 326 | Women's Health Study | All n-3 FA: $10.4 \mathrm{~g} / \mathrm{d}$ |
| 327 | Women's Health Study | All n-3 FA: $10.4 \mathrm{~g} / \mathrm{d}$ |
| 328 | Women's Health Study | All n-3 FA: $10.4 \mathrm{~g} / \mathrm{d}$ |
| 329 | Women's Health Study | All n-3 FA: 6.05\% FA |

Causality Table: Observational Studies

| Row | Study | n-3 source | n -3 measure | n -3 type(s) |
| :---: | :---: | :---: | :---: | :---: |
| 323 | Women's Health Initiative | intake | g/d | DHA + EPA |
| 324 | Women's Health Initiative | intake | g/d | ALA |
| 325 | Women's Health Study | intake | g/d | all n-3 |
| 326 | Women's Health Study | intake | g/d | ALA |
| 327 | Women's Health Study | intake | g/d | EPA |
| 328 | Women's Health Study | intake | g/d | DHA |
| 329 | Women's Health Study | erythrocyte | \% of total FA | cis n-3 PUFA |

## Causality Table: Observational Studies

| Row Study | Study design |  |
| :--- | :--- | :--- |
| 323 | Women's Health Initiative | Prospective, longitudinal study of intake (eg, FFQ, biomarker) |
| 324 | Women's Health Initiative |  |
|  |  |  |
|  |  |  |
| 325 | Women's Health Study |  |
| 326 | Women's Health Study | Prospective, longitudinal study of intake (eg, FFQ, biomarker) |
| 327 | Women's Health Study | Prospective, longitudinal study of intake (eg, FFQ, biomarker) |
| 328 | Women's Health Study | Prospective, longitudinal study of intake (eg, FFQ, biomarker) |
| 329 | Women's Health Study | Nested Case Control |
|  |  |  |

Causality Table: Observational Studies

| Row | Study | Outcome | Reported effect Size |
| :--- | :--- | :--- | :--- |
| 323 | Women's Health Initiative | Congestive heart failure | See appendix F |
|  |  |  |  |
| 324 | Women's Health Initiative | Congestive heart failure | See appendix F |
