This report is based on research conducted by the Johns Hopkins University Evidence-based Practice Center (EPC) under contract to the Agency for Healthcare Research and Quality (AHRQ), Rockville, MD (Contract No. 290-2015-00006-I). The findings and conclusions in this document are those of the authors, who are responsible for its contents; the findings and conclusions do not necessarily represent the views of AHRQ. Therefore, no statement in this report should be construed as an official position of AHRQ or of the U.S. Department of Health and Human Services.

None of the investigators have any affiliations or financial involvement that conflicts with the material presented in this report.

The information in this report is intended to help healthcare decision makers—patients and clinicians, health system leaders, and policymakers, among others—make well-informed decisions and thereby improve the quality of healthcare services. This report is not intended to be a substitute for the application of clinical judgment. Anyone who makes decisions concerning the provision of clinical care should consider this report in the same way as any medical reference and in conjunction with all other pertinent information, i.e., in the context of available resources and circumstances presented by individual patients.

This report is made available to the public under the terms of a licensing agreement between the author and the Agency for Healthcare Research and Quality. This report may be used and reprinted without permission except those copyrighted materials that are clearly noted in the report. Further reproduction of those copyrighted materials is prohibited without the express permission of copyright holders.

AHRQ or U.S. Department of Health and Human Services endorsement of any derivative products that may be developed from this report, such as clinical practice guidelines, other quality enhancement tools, or reimbursement or coverage policies, may not be stated or implied.

AHRQ appreciates appropriate acknowledgment and citation of its work. Suggested language for acknowledgment: This work was based on an evidence report, Integrating Palliative Care in Ambulatory Care of Noncancer Serious Chronic Illness, by the Evidence-based Practice Center Program at the Agency for Healthcare Research and Quality (AHRQ).

Preface

The Agency for Healthcare Research and Quality (AHRQ), through its Evidence-based Practice Centers (EPCs), sponsors the development of systematic reviews to assist public- and private-sector organizations in their efforts to improve the quality of healthcare in the United States. These reviews provide comprehensive, science-based information on common, costly medical conditions, and new healthcare technologies and strategies.

Systematic reviews are the building blocks underlying evidence-based practice; they focus attention on the strength and limits of evidence from research studies about the effectiveness and safety of a clinical intervention. In the context of developing recommendations for practice, systematic reviews can help clarify whether assertions about the value of the intervention are based on strong evidence from clinical studies. For more information about AHRQ EPC systematic reviews, see www.effectivehealthcare.ahrq.gov/about/epc/evidence-synthesis.

AHRQ expects that these systematic reviews will be helpful to health plans, providers, purchasers, government programs, and the healthcare system as a whole. Transparency and stakeholder input are essential to the Effective Health Care Program. Please visit the website (www.effectivehealthcare.ahrq.gov) to see draft research questions and reports or to join an email list to learn about new program products and opportunities for input.

If you have comments on this systematic review, they may be sent by mail to the Task Order Officer named below at: Agency for Healthcare Research and Quality, 5600 Fishers Lane, Rockville, MD 20857, or by email to epc@ahrq.hhs.gov.

Key Informants

In designing the study questions, the EPC consulted several Key Informants who represent the end-users of research. The EPC sought the Key Informant input on the priority areas for research and synthesis. Key Informants are not involved in the analysis of the evidence or the writing of the report. Therefore, in the end, study questions, design, methodological approaches, and/or conclusions do not necessarily represent the views of individual Key Informants.

Key Informants must disclose any financial conflicts of interest greater than \$5,000 and any other relevant business or professional conflicts of interest. Because of their role as end-users, individuals with potential conflicts may be retained. The TOO and the EPC work to balance, manage, or mitigate any conflicts of interest.

The list of Key Informants who provided input to this report follows:

Patricia Adams, M.S.N., ANP*
Patricia Porter Adams, LLC
Alexandria, VA

Melinda Ashton, M.D.
(AHRQ Learning Health System Panel)
Hawaii Pacific Health

Technical Expert Panel

In designing the study questions and methodology at the outset of this report, the EPC consulted several technical and content experts. Broad expertise and perspectives were sought. Divergent and conflicted opinions are common and perceived as healthy scientific discourse that results in a thoughtful, relevant systematic review. Therefore, in the end, study questions, design, methodologic approaches, and/or conclusions do not necessarily represent the views of individual technical and content experts.

Technical Experts must disclose any financial conflicts of interest greater than \$5,000 and any other relevant business or professional conflicts of interest. Because of their unique clinical or content expertise, individuals with potential conflicts may be retained. The TOO and the EPC work to balance, manage, or mitigate any potential conflicts of interest identified.

The list of Technical Experts who provided input to this report follows:

Marian Grant, D.N.P., C.R.N.P.*
Coalition to Transform Advanced Care
Washington, DC

Dio Kavalieratos, Ph.D.
University of Pittsburgh
Pittsburgh, PA

Dale Lupu, Ph.D., M.P.H.*

Seattle, WA

Tracy A. Schroepfer, Ph.D., M.S.W.*
University of Wisconsin-Madison
Madison, WI

*Provided input on Draft Report.

Peer Reviewers

Prior to publication of the final evidence report, EPCs sought input from independent Peer Reviewers without financial conflicts of interest. However, the conclusions and synthesis of the scientific literature presented in this report do not necessarily represent the views of individual reviewers.

Peer Reviewers must disclose any financial conflicts of interest greater than \$5,000 and any other relevant business or professional conflicts of interest. Because of their unique clinical or content expertise, individuals with potential nonfinancial conflicts may be retained. The TOO and the EPC work to balance, manage, or mitigate any potential nonfinancial conflicts of interest identified.

The list of Peer Reviewers follows:

Integrating Palliative Care in Ambulatory Care of Noncancer Serious Chronic Illness

Structured Abstract

Objectives. To evaluate availability, effectiveness, and implementation of interventions for integrating palliative care into ambulatory care for U.S.-based adults with serious life-threatening chronic illness or conditions other than cancer and their caregivers. We evaluated interventions addressing identification of patients, patient and caregiver education, shared decision-making tools, clinician education, and models of care.

Data sources. We searched key U.S. national websites (March 2020) and PubMed®, CINAHL®, and the Cochrane Central Register of Controlled Trials (through May 2020). We also engaged Key Informants.

Review methods. We completed a mixed-methods review; we sought, synthesized, and integrated Web resources; quantitative, qualitative and mixed-methods studies; and input from patient/caregiver and clinician/stakeholder Key Informants. Two reviewers screened websites and search results, abstracted data, assessed risk of bias or study quality, and graded strength of evidence (SOE) for key outcomes: health-related quality of life, patient overall symptom burden, patient depressive symptom scores, patient and caregiver satisfaction, and advance directive documentation. We performed meta-analyses when appropriate.

Results. We included 46 Web resources, 20 quantitative effectiveness studies, and 16 qualitative implementation studies across primary care and specialty populations. Various prediction models, tools, and triggers to identify patients are available, but none were evaluated for effectiveness or implementation. Numerous patient and caregiver education tools are available, but none were evaluated for effectiveness or implementation. All of the shared decision-making tools addressed advance care planning; these tools may increase patient satisfaction and advance directive documentation compared with usual care (SOE: low). Patients and caregivers prefer advance care planning discussions grounded in patient and caregiver experiences with individualized timing. Although numerous education and training resources for nonpalliative care clinicians are available, we were unable to draw conclusions about implementation, and none have been evaluated for effectiveness. The models evaluated for integrating palliative care were not more effective than usual care for improving health-related quality of life or patient depressive symptom scores (SOE: moderate) and may have little to no effect on increasing patient satisfaction or decreasing overall symptom burden (SOE: low), but models for integrating palliative care were effective for increasing advance directive documentation (SOE: moderate). Multimodal interventions may have little to no effect on increasing advance directive documentation (SOE: low) and other graded outcomes were not assessed. For utilization, models for integrating palliative care were not found to be more effective than usual care for decreasing hospitalizations; we were unable to draw conclusions about most other aspects of utilization or cost and resource use. We were unable to draw conclusions about caregiver satisfaction or specific characteristics of models for integrating palliative care. Patient preferences for

appropriate timing of palliative care varied; costs, additional visits, and travel were seen as barriers to implementation.

Conclusions. For integrating palliative care into ambulatory care for serious illness and conditions other than cancer, advance care planning shared decision-making tools and palliative care models were the most widely evaluated interventions and may be effective for improving only a few outcomes. More research is needed, particularly on identification of patients for these interventions; education for patients, caregivers, and clinicians; shared decision-making tools beyond advance care planning and advance directive completion; and specific components, characteristics, and implementation factors in models for integrating palliative care into ambulatory care.

Evidence Summary

Main Points

For integrating palliative care into ambulatory care for adults with serious life-threatening chronic illness and conditions other than cancer in U.S. settings:

- A variety of resources exist, particularly for patient and caregiver education and clinician education and training, but few have been evaluated for effectiveness or implementation.
- Shared decision-making tools may increase patient satisfaction and advance directive documentation.
- The models evaluated for integrating palliative care may have little to no effect on reducing overall symptom burden and were not more effective than usual care for improving health-related quality of life or depressive symptom scores but were more effective for increasing advance directive documentation.
- Patients and caregivers prefer advance care planning discussions grounded in patient and caregiver experiences and individualized for timing.

Background and Purpose

In the United States, most care for adults with serious life-threatening chronic illness or conditions (e.g., advanced heart failure, chronic obstructive pulmonary disease, or end-stage renal disease) occurs in ambulatory settings. Care for these patients can be complex, as the patients often experience high symptom burden and decreased health-related quality of life. Patients may benefit from the integration of palliative care into ambulatory care that is made possible either through the incorporation of palliative care services or by training ambulatory care clinicians in palliative care.

The key decisional dilemma for clinicians, patients, and caregivers is “How can people with serious life-threatening chronic illness or conditions best receive ambulatory care that integrates appropriate palliative care approaches or educational services, materials, or shared decision-making tools?” An existing recent systematic review addresses integrating palliative care into ambulatory oncology, so this review focuses on other serious chronic illness and conditions.

Methods

We completed a mixed-methods review focusing on serious chronic illnesses other than cancer; we synthesized and integrated evidence from key U.S. national websites (March 2020), quantitative effectiveness and qualitative implementation studies, and input from patient/caregiver and clinician/stakeholder Key Informants. We completed searches for studies in May 2020. With input from the stakeholders and experts, we considered effectiveness as those outcomes that are within the domains of palliative care and have evidence for associations with positive patient and caregiver outcomes. We performed meta-analyses when appropriate.

Results

For each of the Key Questions below, we addressed three parts:

- What is available?
- What is the effectiveness?

- How is it implemented?

We then integrated these parts for each Key Question.

We included 46 Web resources, 20 quantitative effectiveness studies and 16 qualitative implementation studies. We identified no mixed-methods studies.

Key Question 1. How can we identify those patients who could benefit from palliative care in ambulatory care settings, and what is the evidence for effectiveness and implementation of these methods?

- A variety of potential prediction models, tools, and triggers are available, mainly for general populations rather than specific illnesses or conditions, but none were evaluated for effectiveness or implementation.
- Multimodal intervention studies have included triggers together with shared decision-making tools for primary care and advanced heart failure.
- Clinician/stakeholder Key Informants perceived that methods for patient identification and selection, such as triggering/reminder systems, are helpful, and that time and space to introduce palliative care in the ambulatory care setting is critical.
- Patient/caregiver Key Informants felt that palliative care options should be provided early and offered to all patients with serious illnesses.

Key Question 2. What educational resources are available for patients and caregivers in ambulatory care about integrating palliative care, and what is the evidence for their effectiveness and implementation?

- Although a variety of relevant patient and caregiver education tools are available, mainly for general populations rather than specific illnesses or conditions, none were evaluated for effectiveness or implementation.
- Only one of the nine models for integrating palliative care that were evaluated for effectiveness included patient/caregiver education as a component.
- Patient/caregiver Key Informants felt that education was very important, that clinicians should initiate discussions face-to-face and that clarifying the definition of palliative care is key. They also felt that these discussions should be done in a patient-friendly, easily understandable manner and format, aided by educational materials.

Key Question 3. What palliative care shared decision-making tools for serious life-threatening chronic illness or conditions are available for clinicians, patients, and caregivers in ambulatory care, and what is the evidence for their effectiveness and implementation?

- All identified shared decision-making tools addressed advance care planning only.
- Shared decision-making tools may improve patient satisfaction with communication and increase advance directive documentation compared with usual care (SOE: Low for both).
- We were unable to draw conclusions about the effectiveness of shared decision-making tools for patient symptoms of depression or caregiver satisfaction.
- Qualitative evidence supported grounding advance care planning in patient and caregiver experiences of illness, and this was a key component of several of the shared decision-making tools that were evaluated for effectiveness.
- Time constraints, resources, and integration into workflow were raised as concerns in implementation; all shared decision-making tools involved additional personnel and resources.

Key Question 4. What educational resources are available for nonpalliative care clinicians about integrating palliative care in ambulatory settings, and what is the evidence for their effectiveness and implementation?

- Although a variety of relevant clinician education and training resources for nonpalliative care clinicians are available, only one implementation study explicitly evaluated this component, and only one effectiveness study included this component.
- Both clinician/stakeholder and patient/caregiver Key Informants expressed that more education and training is needed for ambulatory care clinicians; patients/caregivers indicated that listening skills are especially important.

Key Question 5. What are the models for integrating palliative care into ambulatory settings, and what is the evidence for their effectiveness and implementation?

- The models evaluated for integrating palliative were not more effective than usual care for patient health-related quality of life (strength of evidence [SOE]: Moderate).
- The models evaluated for integrating palliative care may have little to no effect compared with usual care for overall symptom burden (SOE: Low) and were not more effective than usual care for depressive symptom scores (SOE: Moderate).
- The models evaluated for integrating palliative care may have little to no effect compared with usual care on patient satisfaction (SOE: Low), and no studies addressed caregiver satisfaction.
- The models evaluated for integrating palliative care were more effective than usual care for increasing advance directive documentation (SOE: Moderate).
- For utilization, the models evaluated for integrating palliative were not more effective than usual care for reducing hospitalizations; we were unable to draw conclusions about most other aspects of utilization or cost and resource use.

- Multimodal interventions may have little to no effect on increasing advance directive documentation (SOE: Low), and no studies addressed the effect of multimodal interventions for other critical (graded) outcomes.
- Multimodal interventions (including combinations of identification of patients, education for patients and caregivers, shared decision-making tools, and education for nonpalliative care clinicians) had little to no effect on advance directive documentation (SOE: Low) and no studies addressed the effect of multimodal interventions for other critical (graded) outcomes.
- A wide variety of components, characteristics, and factors have been implemented in models for integrating palliative care and are perceived as important by patients, caregivers, clinicians, and stakeholders, but we were unable to draw conclusions about which, if any, of these influence effectiveness or implementation.
- Clinician/stakeholder Key Informants had a number of suggestions for implementation of models and multimodal interventions for integrating palliative care, including integration into and simplification of workflows and documentation, leveraging delivery systems and payment mechanisms, use of interdisciplinary care, and integrating quality measurement and improvement.
- Patient/caregiver Key Informants indicated that clinicians should integrate palliative care into routine care, and that primary care is a key opportunity to introduce it.

Strengths and Limitations

The studies evaluating the effectiveness and implementation of shared decision-making tools focused only on aspects of advance care planning, and included a wide variety of shared tools and models for integrating palliative care across primary care and specialty settings. Studies addressed primary care and common serious illnesses, but none addressed the important ambulatory palliative care issues of multimorbidity or frailty or issues of health equity. Although Web resources exist for identification of patients, patient and caregiver educational materials, and clinician education and training, little evidence for effectiveness or implementation exists for these types of interventions. Key study limitations included issues with blinding of outcomes assessment and variations in outcome reporting (particularly for cost and resource use) in quantitative studies and lack of sufficient rigor in qualitative studies. No studies reported burdens or adverse effects of interventions. Although implementation evidence describes key components and characteristics of models for integrating palliative care and factors in shared decision-making tool and model implementation, evidence for patient/caregiver perspectives on factors in model implementation was limited and we were unable to draw conclusions on the effectiveness of specific components and characteristics, or in specific populations or settings.

Implications and Conclusions

For integrating palliative care into ambulatory care, shared decision-making tools may increase patient satisfaction and advance directive documentation. Models for integrating palliative care may have little to no effect on overall symptom burden and were not effective for patient health-related quality of life or depressive symptom scores, but did increase advance directive documentation. Given the investments needed for these types of interventions with little to no effectiveness for patient-centered outcomes, more research is particularly needed on the effectiveness on patient outcomes of identification of patients for palliative care; educational

materials for patients, caregivers, and clinician; and specific types, components, and characteristics of models for integrating palliative care.

Introduction

Background

Most care for adults with serious life-threatening chronic illness or conditions occurs in ambulatory settings, particularly in clinicians' offices. Care for these patients can be complex, because patients often experience high symptom burden and other needs and decreased health-related quality of life. Patients may benefit from integration of palliative care into ambulatory care, either through the incorporation of palliative care services or by training ambulatory care clinicians in palliative care competencies. Palliative care can be defined as "care, services, or programs for patients with serious life-threatening illness and their caregivers, with the primary intent of relieving suffering and improving health-related quality of life, including dimensions of physical, psychological/ emotional, social, and spiritual well-being."¹ Palliative care interventions aim to address outcomes such as patient symptoms; advance care planning and goals of care communication; patient and caregiver satisfaction; and potentially burdensome healthcare utilization, such as hospitalizations.

Populations with serious life-threatening chronic illness and conditions of key interest for palliative care include, but are not limited to, those with advanced heart failure [New York Heart Association (NYHA) class III or IV], advanced chronic obstructive pulmonary disease [Global Initiative for Chronic Obstructive Lung Disease (GOLD) stage III or IV], end-stage renal disease (older patients on dialysis or choosing not to have dialysis), and those with frailty or multiple serious chronic conditions.² Cancer is also a key area of interest for integrating palliative care but, because an existing recent systematic review already addresses integrating palliative care into ambulatory oncology, this review focuses on other illnesses and conditions.³

The key decisional dilemma for health systems, clinicians, patients, and family caregivers (noted hereafter as "caregivers") is the following: "How can people with serious life-threatening chronic illness or conditions best receive ambulatory care that integrates appropriate palliative care approaches?" Given the significant investments and competing needs for health systems and clinicians in palliative care along with the costs and burdens for patients and caregivers, the evaluation of patient- and caregiver-centered outcomes, utilization, costs, and burden is important. A variety of types of interventions can be implemented, separately or together, to better integrate palliative care into ambulatory care for this population.

Interventions

Identification of patients. Approaches to identifying ambulatory patients who could benefit from palliative care include triggers or prediction models or tools.⁴ These approaches may incorporate patient or illness characteristics; recent hospitalizations; indicators of serious illness or worsening of illness, such as worsening functional status; or patient-reported measures to identify patients who may have needs that could be addressed with palliative care approaches.

Patient and caregiver educational materials and resources. Educational materials about integrating palliative care and palliative care options in ambulatory care such as pamphlets, Web sources, and videos are available from a variety of organizations focusing on palliative care as well as specific conditions. Some evidence supports the effectiveness of patient education for increasing patient acceptance of palliative care.⁵

Shared decision-making tools. Shared decision-making tools are patient-facing and/or clinician-facing tools to help people make decisions for domains such as advance care planning

or symptom management for relevant populations in ambulatory care.⁶ Advance care planning, or communication about serious illness care goals, is defined by the American College of Physicians as a key task in ambulatory care that should occur throughout the course of a serious illness.² Relevant tools may include advance care planning guides, such as advance directive forms, patient and clinician educational materials, and Web- and video-based interventions focused on serious illness and conditions.

Clinician education. National palliative care organizations and other types of organizations have developed trainings and education materials that include content about integrating palliative care into ambulatory care to educate both palliative care and nonpalliative care clinicians.

Models for integrating palliative care into ambulatory care and multimodal interventions. Successful models for integrating palliative care approaches with primary and other ambulatory care address 1) the complexity of care and needs in cases of serious illness and 2) coordination with broader health systems.⁷ Key models for integrating palliative care include shared care (where palliative care clinicians work together with other ambulatory clinicians to meet patients' palliative care needs), consultative care (where nonpalliative care ambulatory clinicians address common palliative care needs, with referrals to specialty palliative care when needs are more complex or are not being met), and the use of supplementary care coordinators or social workers in care. Multimodal interventions, for the purposes of this review, are defined as combinations of the different types of included specific interventions: identification of patients, education for patients and caregivers, shared decision-making tools, and education for nonpalliative care clinicians.

Purpose of the Review

We addressed five questions about the integration of palliative care in ambulatory care for patients with serious life-threatening chronic illness or conditions other than cancer:

1. How can we identify those patients who could benefit from palliative care in ambulatory care settings?
2. What educational resources are available for patients and caregivers in ambulatory care about palliative care?
3. What palliative care decision-making tools are available for clinicians, patients, and caregivers in ambulatory care?
4. What educational resources are available for nonpalliative care clinicians about palliative care in ambulatory settings?
5. What are the models for integrating palliative care into ambulatory settings?

For each of these questions we addressed three parts:

- What is available?
- What is the effectiveness?
- How is it implemented?

Methods

Review Approach

This mixed methods review includes a grey literature search and systematic reviews of the published quantitative and qualitative, mixed-methods, and process evaluation literature, as well as an integration of results across these sources and review methods. We followed the methods outlined in the Agency for Healthcare Research and Quality's (AHRQ's) Methods Guide for Effectiveness and Comparative Effectiveness Reviews (refer to the Methods Appendix for additional details). We have reported the results of the systematic review in accordance with the Preferred Items for Reporting in Systematic Reviews and Meta-Analyses (PRISMA).⁸ Integrative review methods are based on the 2017 Cochrane guidance, *Qualitative and Implementation Methods Group Guidance Paper 5: Methods for integrating qualitative and implementation evidence within intervention effectiveness reviews*,⁹ and the Joanna Briggs Institute methods for mixed methods systematic reviews.¹⁰

AHRQ developed the topic of this systematic review. We recruited Key Informants (KIs) to refine the topic and Key Questions and provide input on the integration of results. We recruited a Technical Expert Panel (TEP) to provide input on all details of the protocol, including outcomes. The KIs and TEP represented palliative care, primary care, and other ambulatory specialties, and included physicians, nurses, and social workers; we also included patient advocate KIs. With the feedback from the TEP, KIs, AHRQ, and our partners, the National Institute for Nursing Research, and the Health Resources and Services Administration, we finalized the protocol and posted it on the AHRQ Effective Health Care Program's website (www.effectivehealthcare.ahrq.gov).

Key Questions

Key Question (KQ) 1. How can we identify those patients who could benefit from palliative care in ambulatory care settings, and what is the evidence for effectiveness and implementation of these methods?

KQ1a. What prediction models, tools, triggers, and guidelines and position statements are available about how to identify when and which patients with serious life-threatening chronic illness or conditions in ambulatory settings could benefit from palliative care?

KQ1b. What is the effectiveness of prediction models, tools, and triggers for identifying when and which patients with serious life-threatening chronic illness or conditions in ambulatory settings could benefit from palliative care?

KQ1c. How have prediction models, tools, and triggers for identifying when and which patients with serious life-threatening chronic illness or conditions in ambulatory settings could benefit from palliative care been implemented? What is the evidence for how, when, and for which patients they could best be implemented in care?

Key Question 2. What educational resources are available for patients and caregivers in ambulatory care about integrating palliative care, and what is the evidence for their effectiveness and implementation?

KQ2a. What educational materials and resources are available about palliative care and palliative care options for patients with serious life-threatening chronic illness or conditions in ambulatory settings and their caregivers?

KQ2b. What is the effectiveness of educational materials and resources about palliative care and palliative care options for patients with serious life-threatening chronic illness or conditions and their caregivers in ambulatory settings?

KQ2c. How have educational materials and resources about palliative care and palliative care options for patients with serious life-threatening chronic illness or conditions and their caregivers in ambulatory settings been implemented? What is the evidence for how, when, and for which patients and caregivers they could best be implemented in care?

Key Question 3. What palliative care shared decision-making tools for serious life-threatening chronic illness or conditions are available for clinicians, patients, and caregivers in ambulatory care, and what is the evidence for their effectiveness and implementation?

KQ3a. What palliative care shared decision-making tools are available for patients with serious life-threatening chronic illness or conditions in ambulatory settings and their caregivers?

KQ3b. What is the effectiveness of palliative care shared decision-making tools for patients with serious life-threatening chronic illness or conditions in ambulatory settings and their caregivers?

KQ3c. How have palliative care shared decision-making tools been implemented for patients with serious life-threatening chronic illness or

conditions in ambulatory settings and their caregivers? What is the evidence for how, when, and for which patients and caregivers they could best be implemented in care?

Key Question 4. What educational resources are available for nonpalliative care clinicians about integrating palliative care in ambulatory settings, and what is the evidence for their effectiveness and implementation?

KQ4a. What palliative care training and educational materials are available for nonpalliative care clinicians caring for patients with serious life-threatening chronic illness or conditions in ambulatory settings?

KQ4b. What is the effectiveness of palliative care training and educational materials (with or without other intervention components) for nonpalliative care clinicians caring for patients with serious life-threatening chronic illness or conditions in ambulatory settings?

KQ4c. How have palliative care training and educational materials (with or without other intervention components) for nonpalliative care clinicians caring for patients with serious life-threatening chronic illness or conditions in ambulatory settings been implemented? What is the evidence for how, when, and for which clinicians they could best be implemented in care?

Key Question 5. What are the models for integrating palliative care into ambulatory settings, and what is the evidence for their effectiveness and implementation?

KQ5a. What models and multimodal interventions for integrating palliative care have been developed for patients with serious life-threatening chronic illness or conditions in ambulatory settings?

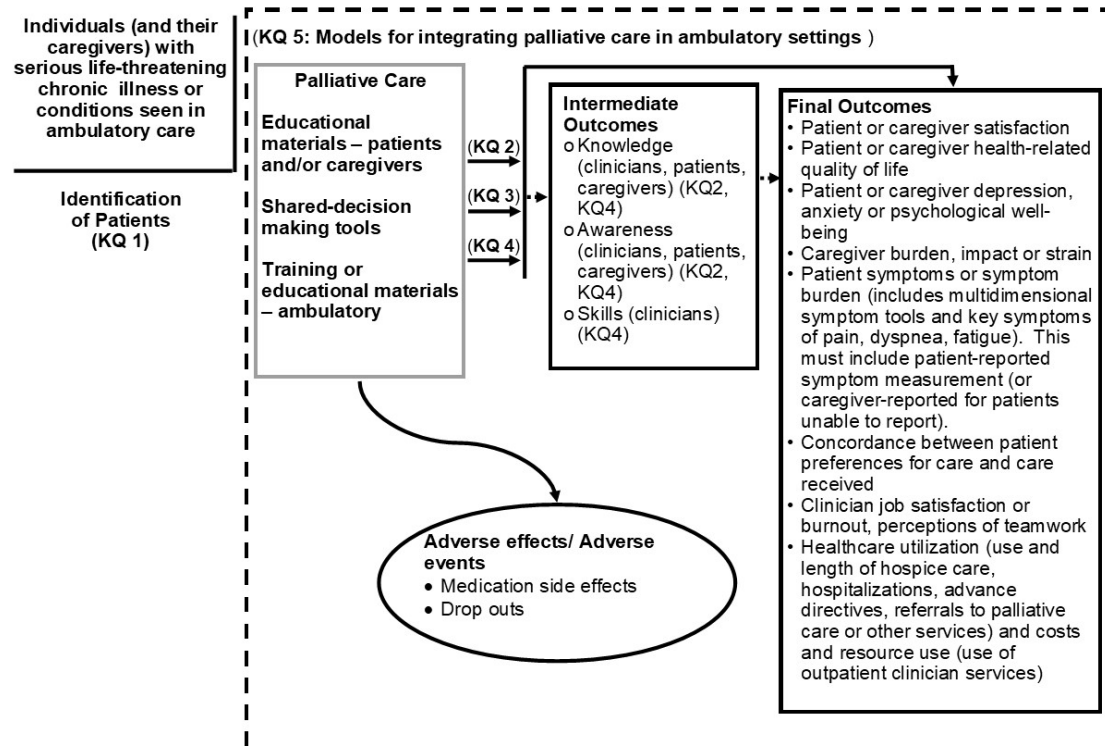

KQ5b. What is the effectiveness of models and multimodal interventions for integrating palliative care for patients with serious life-threatening chronic illness or conditions in ambulatory settings?

KQ5c. What are components of models and multimodal interventions for integrating palliative care in ambulatory settings? What models and multimodal interventions have been implemented for key subpopulations? What components and characteristics of these models and multimodal interventions contribute to their effective implementation? What is the evidence for how, when, and for which patients they could best be implemented in care?

Analytic Framework

Figure 1 displays the analytic framework. With input from the stakeholders and experts, we considered effectiveness as those outcomes that are within the domains of palliative care and have evidence for associations with patient and caregiver outcomes.

Figure 1. Analytic framework for integrating palliative care in ambulatory care of noncancer serious chronic illness

KQ = Key Question

Study Selection

We searched PubMed®, CINAHL®, and the Cochrane Central Register of Controlled Trials in May 2020. Two team members independently applied eligibility criteria (Table 1 and Table 2) to citations identified by these searches. In March 2020, we searched key U.S. national websites identified as relevant to the Key Questions and refined with input from AHRQ and Technical Experts, including websites from palliative care organizations, primary care and specialty healthcare professional organizations, government organizations, foundations with a major focus in palliative care, and patient organizations (see Methods Appendix A for full list of websites searched). Two reviewers simultaneously screened available website content for eligibility based on the Population, Intervention, Comparisons, Outcomes, Type of study, Setting (PICOTS); specific relevance to integrating palliative care into ambulatory care in the United States; and our criterion that materials must have been developed or updated within the last 5 years. Full details on the search strategy and eligibility criteria are in Methods Appendix A.

Table 1. PICOTS: Inclusion and exclusion criteria for quantitative studies relevant to integrating palliative care into ambulatory care for serious life-threatening chronic illness or conditions

PICOTS	Inclusion	Exclusion
Population	<ul style="list-style-type: none"> Patients (≥ 18 years of age) with serious life-threatening chronic illness or conditions (other than those only with cancer) and their caregivers, being seen in ambulatory settings (KQs 1,2,3,5) Clinicians practicing in ambulatory settings (KQ4) 	<ul style="list-style-type: none"> Studies with only cancer patients Studies not focusing on ambulatory populations Studies of clinicians caring only for cancer patients Studies focusing on trainees
Interventions	<p>KQ1: prediction models, tools, or triggers to identify patients for palliative care in ambulatory settings</p> <p>KQ2: educational materials and resources about palliative care for patients and/or caregivers in ambulatory settings</p> <p>KQ3: palliative care shared decision-making tools and resources for clinicians and patients and/or caregivers in ambulatory settings</p> <p>KQ4: palliative care training or educational materials for ambulatory settings</p> <p>KQ5: models for integrating palliative care or multimodal interventions in ambulatory settings</p>	<ul style="list-style-type: none"> Studies that report no intervention of interest
Comparisons	<p>KQ1: prediction models, tools, or triggers to identify patients for palliative care in ambulatory settings</p> <p>KQ2: educational materials and resources about palliative care for patients and/or caregivers in ambulatory settings</p> <p>KQ3: palliative care shared decision-making tools and resources for clinicians and patients and/or caregivers in ambulatory settings</p> <p>KQ4: palliative care training or educational materials for ambulatory settings</p> <p>KQ5: models for integrating palliative care or multimodal interventions in ambulatory settings</p> <p>Usual care for all KQs</p>	<ul style="list-style-type: none"> Studies that do not report the comparisons of interest*

PICOTS	Inclusion	Exclusion
Outcomes	<p>Intermediate</p> <ul style="list-style-type: none"> Knowledge (clinicians, patients, caregivers) (KQ2, KQ4) Awareness (clinicians, patients, caregivers) (KQ2, KQ4) Skills (clinicians) (KQ4) <p>Final (All apply to all KQ) (In hierarchy from patient-centered to clinician to health system. All patient- or caregiver-reported outcomes must be measured by a validated instrument.¹¹)</p> <ul style="list-style-type: none"> Patient or caregiver satisfaction Patient or caregiver health-related quality of life Patient or caregiver symptoms of depression, anxiety, or psychological well-being Caregiver burden, caregiver impact, or caregiver strain Patient symptoms or symptom burden (includes multidimensional symptom tools and key symptoms of pain, dyspnea, fatigue); this must include patient-reported symptom measurement (or caregiver-reported for patients unable to report) Concordance between patient preferences for care and care received Clinician job satisfaction or burnout, perceptions of teamwork Healthcare utilization (use and length of hospice care, hospitalizations, advance directive documentation) and costs and resource use (use of outpatient clinician services, including palliative care) <p>Adverse effects</p> <ul style="list-style-type: none"> Medication side effects Dropouts related to the intervention 	<ul style="list-style-type: none"> Studies that do not report the outcomes of interest Excludes clinician self-report for intermediate outcomes

*Comparisons to other included interventions or to usual care.

PICOTS= Population, Intervention, Comparisons, Outcomes, Type of study, Setting; KQ=Key Questions

Table 2. Additional inclusion and exclusion criteria for qualitative, mixed-methods, and process evaluation studies

Criteria	Inclusion	Exclusion
Comparison	No comparison group needed	No exclusion
Type of study	<ul style="list-style-type: none"> • Systematic reviews of qualitative studies • Qualitative or mixed-methods studies: including studies that use a formal qualitative data collection method (e.g., interviews, focus groups, ethnography) and analysis methods (e.g., phenomenological, grounded theory, ethnographic and thematic analysis studies) • Process evaluation studies (type of implementation studies) including studies that address the following in results: <ul style="list-style-type: none"> ○ Identifying/addressing barriers/facilitators ○ Populations to target ○ Mechanisms for success/failure 	<ul style="list-style-type: none"> • Qualitative studies: observation or artifact analysis • Process evaluation studies focusing only on research issues (e.g., fidelity, participant recruitment, intervention quality, participant engagement)
Sample size		<ul style="list-style-type: none"> • Analysis of interest includes fewer than 10 participants

Data Extraction and Risk of Bias Assessment

Paired investigators abstracted data sequentially. For quantitative studies, reviewers assessed risk of bias independently. We used the Cochrane Risk of Bias Tool, Version 2, for assessing the risk of bias of randomized controlled trials (RCTs).¹² For non-randomized studies, we used the Cochrane Risk of Bias Assessment Tool for Non-Randomized Studies of Interventions (ROBINS-I) tool.¹³ For qualitative and mixed-methods studies, reviewers independently assessed study quality using the Joanna Briggs Institute Checklist^{14, 15} (see Methods Appendix A for more details).

In addition to seeking feedback from the Key Informants on the Key Questions, we engaged two separate groups of Key Informants to provide input on the integrative review process: one group of patients and caregivers; and one group of stakeholders, including practicing clinicians, relevant professional and consumer organizations, purchasers of healthcare, representatives of Learning Health Systems, and others with experience making healthcare decisions. We compiled key issues elicited from the Key Informants and used those to inform our analysis of the qualitative, mixed-methods, and process evaluation literature and the overall integration. At the end of the project, we also conducted sessions with the Key Informants to refine the analysis and integration results.

Data Synthesis and Analysis

We organized the report by Key Question and sub-question. We conducted descriptive synthesis for each Key Question. We conducted meta-analyses when there were sufficient data (i.e., at least three studies) and studies were sufficiently similar with respect to key variables (e.g., population characteristics, study duration, intervention, and outcome measures). When appropriate, we standardized results by estimating the standardized mean difference using the Cohen d method. We used STATA statistical software (Intercooled, version 14, StataCorp, College Station, TX) for all meta-analyses (see Appendix A for details).

We determined clinically meaningful differences for outcome measures wherever possible (see Methods Appendix A for additional details).

We conducted a mixed-methods review in which we completed separate reviews of the different types of evidence, first, and then integrated those results. We completed integration by juxtaposing the findings from a) what is available; with b) the systematic review of quantitative studies (effectiveness); and c) the systematic review of qualitative, mixed-methods, and process evaluation studies (implementation). We used frameworks based on the Consolidated Framework for Implementation From MFRResearch adapted for complex interventions and input from the Key Informants (see Methods Appendix A for additional details).¹⁶

Grading the Strength of the Body of Evidence

We graded the strength of evidence for the systematic review of quantitative studies using the grading scheme recommended by the AHRQ Guide for Conducting Comparative Effectiveness Reviews.¹⁷ We applied evidence grades for the outcomes we classified, with input from our TEP panel, as critical during protocol development, including patient health-related quality of life, patient symptom burden, patient symptoms of depression, patient satisfaction, caregiver satisfaction, and advance directive documentation (see the Methods Appendix A for details regarding the domains assessed, the processes for determining the grades, and the definitions of each grade).

Results

Search Results

We included 46 Web resources specifically addressing integrating palliative care into ambulatory care from the pre-defined key U.S. national websites, 20 quantitative effectiveness studies (n=5,004), and 16 qualitative implementation studies (n>224); we did not identify any mixed-methods studies (see Appendix B for listing of excluded Web resources and studies; Appendix C for listing of included U.S. national Web resources and studies; Appendix Figure C-1 through Figure C-3 for details on the results of the searches and Appendix Table C-1 for summary of key points from Key Informant interviews; and Appendix D for details on the studies, including characteristics of studies and interventions, risk of bias or quality, and strength of evidence).

Below, we summarize parts a, b, and c of each Key Question: what is available, the review of the quantitative effectiveness studies, and the review of the qualitative implementation studies. Finally, we present the integration of these three reviews as well as the patient/caregiver and clinician/stakeholder Key Informant input. We found no studies solely addressing effectiveness of prediction models, tools, or triggers (Key Question 1b), patient and caregiver educational resources (Key Question 2b), or educational resources for clinicians (Key Question 4b). We also found no studies assessing implementation of prediction models, tools, or triggers (Key Question 1c) or patient/caregiver educational resources (Key Question 2c) (see Table 3). Finally, we found no studies addressing the critical outcome of overall patient symptom burden.

Table 3. Resources and studies included in the review*

Intervention Type	Web Resources	Quantitative Effectiveness Studies	Qualitative Implementation Studies
Prediction models, tools, triggers, guidelines and position statements	14	0	0
Patient/ caregiver educational materials and resources	13	0	0
Shared decision-making tools	5	6	5
Nonpalliative care clinician training and educational materials	12	0	1
Models for integrating palliative care	2	12	9
Multimodal interventions	0	2	1
Total	46	20	16

*Two multimodal intervention effectiveness studies included shared decision-making tools and triggers: one model effectiveness study included a significant patient education component, and one model effectiveness study included a significant clinician education component.

Key Subquestion a. What Is Available?

For each Key Question below, we describe included Web resources from the key U.S. national websites and effectiveness or implementation studies relevant to integration of palliative care into ambulatory care for patients with serious life-threatening chronic illness or conditions (see Appendix B for listing of excluded Web resources and studies and Appendix C for listing of included Web resources and studies, and tables 4-8 below list included Web resources).

Key Question 1a. What prediction models, tools, triggers, and guidelines and position statements are available about how to identify when and which patients with serious life-threatening chronic illness or conditions in ambulatory settings could benefit from palliative care?

Table 4. What is available: patient identification (prediction models, tools, and triggers) and guidelines and position statements for integrating palliative care into ambulatory care for patients with serious life-threatening chronic illness or conditions

Key Subquestion b. What Is the Effectiveness?

Key Question 1b. What is the effectiveness of prediction models, tools, and triggers for identifying when and which patients with serious life-threatening chronic illness or conditions in ambulatory settings could benefit from palliative care?

We identified no studies for this Key Question.

Key Question 2b. What is the effectiveness of educational materials and resources about palliative care and palliative care options for patients with serious life-threatening chronic illness or conditions and their caregivers in ambulatory settings?

We identified no studies for this Key Question.

Key Question 3b. What is the effectiveness of palliative care shared decision-making tools for patients with serious life-threatening chronic illness or conditions in ambulatory settings and their caregivers?

Key Points

- All shared decision-making tools evaluated addressed advance care planning.
- Advance care planning shared decision-making tools may be effective for improving patient satisfaction with communication compared with usual care (strength of evidence [SOE]: Low).
- Advance care planning shared decision-making tools may be effective for increasing advance directive documentation compared with usual care (SOE: Low).
- We could not draw conclusions about the effect of advance care planning shared decision-making tools on caregiver satisfaction or patient depressive symptom scores, and no studies addressed other critical outcomes.

Six randomized controlled trials (RCTs) assessed the effectiveness of palliative care shared decision-making tools for patients and caregivers in ambulatory settings (Table 10).^{45-49, 85} These six studies included 1,567 patients (overall range of mean ages was 19 to 83 years) and 58 caregivers (overall mean age was 48 years). Two studies were conducted with end-stage renal disease (ESRD) patients on dialysis; one with ESRD patients on dialysis or with heart failure; one with chronic obstructive pulmonary disease (COPD) patients; and one with multiple serious illnesses, including lung cancer, COPD, heart failure, cirrhosis, and ESRD (Table 9, see Evidence Tables Appendix D for full study characteristics).

Table 9. Characteristics of effectiveness studies assessing shared decision-making tools

Author, Year	Study Characteristics	Intervention Description	Followup Duration
Curtis, et al., 2018 ⁴⁵	n=537 <ul style="list-style-type: none"> Multi-setting, cluster-randomized trial, academic and community setting, primary and specialty care Patients with lung cancer, COPD, heart failure, cirrhosis, or ESRD Government and private funding 	<ul style="list-style-type: none"> Control Group: Enhanced usual care, which included completion of surveys and regular contact with study personnel. Intervention: Jumpstart-Tips. Patients completed survey questions to identify preferences, barriers, and facilitators for communication about end-of-life care. Clinicians received information and communication tips based on the survey. Patients also received a summary of the survey and suggestions for having a goals-of-care conversation with the clinician. Outcomes: Patient satisfaction, symptoms of depression or anxiety, concordance between preferences and care received, and advance directive documentation. 	3 months (2 weeks for patient satisfaction)
Au, et al., 2012 ⁴⁶	n=376 <ul style="list-style-type: none"> Multi-setting, cluster-randomized trial, academic and non-teaching centers Patients with COPD Government funding 	<ul style="list-style-type: none"> Control Group: Control group completed questionnaires but did not receive feedback. Intervention: Patients completed a pre-visit survey addressing preferences, barriers, and facilitators for communication about end-of-life care. Clinicians received a one-page, patient-specific feedback form based on survey responses and communication tips; patients also received a feedback form based on the survey responses. Outcome: Patient satisfaction. 	2 weeks
Kirchhoff, et al., 2012 ⁴⁷	n=313 <ul style="list-style-type: none"> Multi-setting, RCT, academic, community dialysis centers Patients with heart failure or ESRD, and their caregivers Government funding 	<ul style="list-style-type: none"> Control Group: Received usual care; a standard advance directive counseling assessment on admission; and an offering of additional information, if interested. Intervention: Palliative Care - Advance Care Planning, single interview lasting 1 to 1.5 hours to assess patient and caregiver understanding and experience with illness, assist caregiver in preparing to be a decision-maker, and assist in documentation of patient end-of-life preferences using the Statement of Treatment Preferences. Outcome: Concordance between patient preferences and care received. 	Post-death followup control (19-997 days); intervention (5-1,010 days)

Author, Year	Study Characteristics	Intervention Description	Followup Duration
Perry, et al., 2005 ⁴⁸	n=203 <ul style="list-style-type: none"> Multi-setting, 3-arm RCT, academic, 21 dialysis centers, Patients with ESRD Government, non-profit 	<ul style="list-style-type: none"> Control Group arm 1: No study materials, only routine care provided by the dialysis center. Intervention arm 2: Printed materials prepared by the National Kidney Foundation ("Advance Directives: A Guide for Patients and Families") distributed within the 2- to 4-month period. Intervention arm 3: Peer mentoring: 17 peers attended a training workshop to learn about advance directives, assessed through pre-/post-tests and role-playing. Peers contacted patient participants 8 times, which included 5 phone contacts and 3 face-to-face meetings. Outcome: Advance directive documentation. 	2 to 4 months
Song, et al., 2009 ⁴⁹	n=116 <ul style="list-style-type: none"> Multi-Setting, RCT, pre-/post-test, nephrology, community dialysis clinics Patients with ESRD Government funding 	<ul style="list-style-type: none"> Control Group: Received usual care consisting of a clinic social worker providing information on advance directives and rights to have an advance directive on the first day of dialysis treatment. Intervention: Sharing Patients' Illness Representation to Increase Trust (SPIRIT), up to 1-hour, single session interview with a patient-caregiver dyad, delivered by a trained nurse who received competency-based training for 3.5 days, to enhance communication between patients and caregivers about end-of-life care. Outcomes: Patient and caregiver satisfaction. 	3 months
Doorenbos, et al., 2016 ⁸⁵	n=80 <ul style="list-style-type: none"> Single Setting, academic heart failure (HF) clinic RCT, 2 group comparison Patients with heart failure with an ejection fraction (EF) \leq 40% or preserved EF of $<$50% Government, non-profit 	<ul style="list-style-type: none"> Control Group: Received usual care regular scheduled outpatient clinic visits. Intervention: Goal of Care (GOC) communication intervention consisted of phone-based, pre-visit coaching about HF therapies and advance directive completion, delivered by a nurse. Patients and clinicians received a one-page patient summary outline from pre-visit coaching. Outcomes: Patient satisfaction, symptoms of depression and anxiety, advance directive completion. 	2 weeks

COPD = chronic obstructive pulmonary disease; ESRD = end-stage renal disease; RCT = randomized controlled trial; SPIRIT = Sharing Patients' Illness Representation to Increase Trust.

Type	Outcome	Comparison	Number of Studies (N Analyzed)	Findings	Strength of Evidence
Patient-centered outcomes	Patient satisfaction ^{45, 46, 49, 85}	Shared decision-making tools vs. control	4 RCTs (780 participants)	Shared decision-making tools may be effective for improving patient satisfaction with communication compared with usual care.	Low
	Patient symptoms of depression ^{45, 85}	Shared decision-making tools vs. control	2 RCTs (342 participants)	We were unable to draw conclusions.	Insufficient
	Patient symptoms of anxiety ^{45, 85}	Shared decision-making tools vs. control	2 RCTs (407 participants)	We were unable to draw conclusions.	Not graded
	Concordance between patient preferences and care received ^{45, 47}	Shared decision-making tools vs. control	2 RCTs (387 participants)	It is not clear whether the reported differences are meaningful. Shared decision-making tools may be more effective for increasing concordance between patient preferences and care received than usual care.	Not graded
Caregiver-centered outcomes	Caregiver satisfaction ⁴⁹	Shared decision-making tools vs. control	1 RCT (54 participants)	We were unable to draw conclusions.	Insufficient

Type	Outcome	Comparison	Number of Studies (N Analyzed)	Findings	Strength of Evidence
Healthcare utilization	Advance directives documentation ^{45, 48, 85}	Shared decision-making tools vs. printed materials	1 RCT (203 participants) (3 arms)	Advance care planning shared decision-making tools through peer mentoring were more effective than printed materials for increasing advance directives documentation.	Low
		Shared decision-making tools vs. control	3 RCTs (820 participants)	Advance care planning shared decision-making tools were more effective than usual care for advance directives documentation (including goals of care documentation).	Low

RCT = randomized control trial

Patient- and Caregiver-Centered Outcomes

Patient Satisfaction

We identified four RCTs of shared decision-making tools that evaluated patient satisfaction, measured as quality of patient-clinician communication (Table 11).^{45, 46, 49, 85} Two studies evaluated different versions of a patient and clinician feedback intervention to enhance communication in goals of care conversations between clinicians and patients in either COPD⁴⁶ or mixed serious illness populations.⁴⁵ Two studies used a trained nurse interventionist to enhance communication between patients, caregivers, and clinicians. In one of those studies, a nurse provided education to ESRD patients and caregivers about end-of-life care⁴⁹, and in the other study a nurse provided HF patients and clinicians with a summary outline of the pre-visit engagement.⁸⁵ All studies used versions of the Quality of Communication (QOC) questionnaire; three used a version focusing on end-of-life care.^{45, 49, 85}

Of the two feedback trials to enhance communication in goals-of-care conversations, one study (n=376) reported a between-group difference in improvement in the intervention group compared with usual care of 5.7 points, using the QOC questionnaire (100-point scale), (confidence interval [CI] not reported; p=0.03; Cohen effect size, 0.21).⁴⁶ Final results for the other trial (n=268) reported mean values in the intervention and control groups, respectively, of 4.6 and 2.1 points (CI and total score for the scale not reported, p=0.01).⁴⁵ One trial using a trained nurse interventionist to enhance communication about end-of life care did not report baseline results but did report results at the end of the study in the intervention group mean (standard deviation [SD]), 11.30 (1.41) and control group 7.52 (3.66), using the QOC questionnaire (4- to 12-point scale, no statistics reported) (n=56).⁴⁹ The second RCT evaluated the quality of end-of-life communication using the QOC questionnaire (4- to 12-point scale). The trial, using a nurse interventionist, evaluated quality of end-of-life communication in the intervention group 5.76 (3.18) compared with the usual care group 4.47 (2.78) (p=0.03).⁸⁵ We were unable to conduct a meta-analysis owing to incomplete reporting of results and

heterogeneity of interventions. We could not determine if these differences were clinically meaningful. Given the consistent but relatively small differences, we concluded that advance care planning shared decision-making tools may be effective for improving patient satisfaction with communication compared with usual care (SOE: Low).

Caregiver Satisfaction

The RCT (n=54) that used a trained nurse interventionist to enhance communication between ESRD patients and caregivers about end-of-life care also evaluated caregiver satisfaction using the QOC questionnaire (4- to 12-point scale).⁴⁹ The study did not report baseline results but reported results at the end of the study for the intervention group mean (SD) 11.58 (0.72) and control group 10.22 (2.49). Given that there was only one small study with moderate risk of bias, we were unable to draw a conclusion (SOE: Insufficient).

Symptoms of Depression

Two RCTs of a patient and clinician feedback intervention to enhance communication in goals-of-care conversations between clinicians and patients reported symptoms of depression using the Patient Health Questionnaire (PHQ) scale.^{45, 85} One study using the PHQ-8 scale reported results at the end of the study: 4.84 (95% CI, 4.17 to 5.51) in the control group compared with 5.93 (95% CI, 5.05 to 6.81) in the intervention group ($p=0.34$).⁴⁵ The second study, using the PHQ-9 scale, found no change in symptoms of depression in the control group (mean (SD) 5.60 (5.80)) or the intervention group (5.47 (5.03)).⁸⁵ Although there were statistically significant between-group differences for depression in the one small study that reported change with the intervention, the differences were too small to be clinically meaningful. Given imprecise and incomplete reporting of results, we are unable to draw conclusions (SOE: Insufficient).

Symptoms of Anxiety

Two RCTs of a patient and clinician feedback intervention to enhance communication in goals-of-care conversations between clinicians and patients reported symptoms of anxiety using the Generalized Anxiety Disorder-7 scale.^{45, 85} One study reported followup results, only, with 3.08 (95% CI, 2.44 to 3.72) in the control group compared with 3.38 (95% CI, 2.67 to 4.08) in the intervention group ($p=0.85$).⁴⁵ One study found no increase in anxiety using the Generalized Anxiety Disorder scale, post intervention, reporting a mean of 4.15 (4.70) in the control group, and in the intervention group of 3.72 (5.48), $p=0.09$.⁸⁵ This difference was not clinically meaningful. Given imprecise and incomplete reporting of results, we were unable to draw conclusions.

Concordance Between Patient Preferences and Care Received

Two RCTs examined concordance between patient preferences and care received.^{45, 47} One study evaluated an intervention to enhance communication in goals-of-care conversations between clinicians and patients,⁴⁵ and one study used a 1 to 1.5-hour interview intervention conducted by a trained facilitator.⁴⁷ One of these studies, using post-death data for patient participants with a low chance of survival, found receipt of care concordant with initial choices for 46 of the 62 intervention patients (74%) and for 30 of 48 control patients (62%) (no statistics reported).⁴⁷ For the other study, patient-reported goal-concordant care was 70 percent in the intervention group compared with 57 percent in the control group ($p=0.08$).⁴⁵ Shared decision-

making tools may improve concordance between patient preferences and care received, but it is not clear if the reported differences are meaningful.

Healthcare Utilization

Advance Directives Documentation

Three RCTs evaluated the impact of interventions on advance directive or goals-of-care documentation (total n=775). One study evaluated an intervention to enhance communication in goals-of-care conversations between clinicians and patients.⁴⁵ In this study, documentation of goals-of-care conversations occurred in 62 percent of the intervention group compared with 17 percent in the control group ($p<0.001$). One study included two intervention arms for advance directives, one arm using a peer mentoring intervention and one arm using printed material.⁴⁸ In the arm using peer mentoring, completion of the advance directive was 35 percent (22/63) in the intervention group compared with 12 percent (7/59) in the arm using printed material (odds ratio [OR] 0.25; $p<0.05$) and 10 percent (8/81) in the control group (OR 0.20, $p<0.01$).⁴⁸ One smaller study did not find a statistically significant difference between the intervention group 16 percent (7/41) and control group 7.7 percent (3/39) in the completion of advance directives ($p=0.24$).⁸⁵ In three studies, the increases in documentation were consistent and suggest that shared decision-making tools were more effective than usual care for increasing advance directive documentation. (SOE: Low).

Adverse Effects

Dropouts Related to the Intervention

No RCTs reported dropouts related to the intervention.

Key Question 4b. What is the effectiveness of palliative care training and educational materials (with or without other intervention components) for nonpalliative care clinicians caring for patients with serious life-threatening chronic illness or conditions in ambulatory settings?

We identified no studies for this Key Question.

Key Question 5b. What is the effectiveness of models and multimodal interventions for integrating palliative care for patients with serious life-threatening chronic illness or conditions in ambulatory settings?

Key Points

- Models for integrating palliative were not more effective than usual care for improving patient health-related quality of life (HRQOL) (SOE: Moderate).
- Models for integrating palliative care may have little to no effect compared with usual care for reducing overall symptom burden (SOE: Low) and were not more effective than usual care for improving depressive symptom scores (SOE: Moderate).
- Models for integrating palliative care may have little to no effect compared with usual care on increasing patient satisfaction (SOE: Low), and no studies addressed caregiver satisfaction.
- Models for integrating palliative care were more effective than usual care for increasing advance directive documentation (SOE: Moderate).
- Multimodal interventions may have little to no effect on increasing advance directive documentation (SOE: Low), and no studies addressed the effect of multimodal interventions for other critical (graded) outcomes.

Description of Included Studies

We identified 17 articles describing 14 studies assessing the effectiveness of models for integrating palliative care or multimodal interventions for integrating palliative care in ambulatory settings.^{24-26, 67-79, 86} Multimodal interventions, for the purposes of this review, are defined as combinations of the different types of included specific interventions: identification of patients, education for patients and caregivers, shared decision-making tools, and education for nonpalliative care clinicians. These 14 studies included 2,934 patients and 501 caregivers. Nine studies were RCTs and five were controlled (nonrandomized) trials or prospective cohorts. One controlled trial (CT) and one RCT evaluated the effect of multimodal interventions that included a trigger plus clinician training/education. Of the twelve trials assessing models for integrating palliative care, four were shared care models, four involved care coordinators or social workers in care delivery, and four used a consultative model. Followup ranged from 2 weeks to 2 years.

Seven studies were multicenter [Tables 12-17, see Results Appendix D (evidence tables) for full study characteristics].

Table 12. Characteristics of effectiveness studies assessing models for integrating palliative care

Type	Author, Year	Study Characteristics	Intervention Description	Followup Duration
Shared Care Models	Kluger, 2020 ⁶⁷	n=210 patients and n=175 caregivers <ul style="list-style-type: none"> • RCT, multi-center, academic • Patients with Parkinson's disease and related disorders with moderate to high palliative care needs and their caregivers • Nonprofit funding 	<ul style="list-style-type: none"> • Control: Neurologist and primary care practitioner provided standard care. • Intervention: Standard care plus outpatient integrated palliative care delivered by a neurologist, social worker, chaplain, nurse, and palliative medicine specialist. Palliative visits were every 3 months in-person or by telemedicine with as-needed followup phone calls. • Model type: Shared care. 	12 months

Table 17. Summary of effectiveness findings for models for integrating palliative care and multimodal interventions by outcome

Type	Outcome	Comparison	Number of Studies (N at Analysis)	Findings	Strength of Evidence
Patient-centered outcomes	Patient satisfaction ^{70, 74-76}	Models for integrating palliative care vs. usual care	2 RCTs (n=216) 1 CT (n=90)	Models for integrating palliative care may have little to no effect on patient satisfaction compared with usual care.	Low
	Patient HRQOL ^{67, 69-72, 74, 75, 77, 78}	Models for integrating palliative care vs. usual care	6 RCTs (n=897) 2 CTs (n=90+)	Results were consistently not statistically or clinically different between groups. Models for integrating palliative care were not more effective than usual care for HRQOL.	Moderate
	Overall symptom burden ^{67, 71}	Models for integrating palliative care vs usual care	2 RCTs (n=419)	Models for integrating palliative care may have little to no effect on overall symptom burden compared with usual care.	Low
	Patient symptoms of depression ^{67-75, 78}	Models for integrating palliative care vs. usual care	6 RCTs (n=553+) 1 CT (n=90) 2 prospective cohort studies (n=86)	In a pooled analysis of three RCTs ^{67, 70, 78} , we found no difference in symptoms of depression with a model for integrating palliative care compared with usual care (calculated standardized mean difference, -0.09; 95% CI, -0.35 to 0.17). Models for integrating palliative care were not more effective than usual care for symptoms of depression.	Moderate

Type	Outcome	Comparison	Number of Studies (N at Analysis)	Findings	Strength of Evidence
	Patient symptoms of anxiety ^{67-71, 73-75, 78}	Models for integrating palliative care vs. usual care	5 RCTs (n=561) 1 CT (n=90) 2 prospective cohort studies (n=87)	In a pooled analysis of three RCTs ^{67, 70, 78} , we found no differences in anxiety for patients enrolled in a model for integrating palliative care compared with usual care (calculated standardized mean difference, 0.06; 95% CI, -0.2 to 0.32, I-squared=0%). No statistically or clinically significant between-group differences. Models for integrating palliative care were not more effective than usual care for symptoms of anxiety.	Not graded
	Patient psychological well-being ^{67, 69, 74, 75, 77, 78}	Models for integrating palliative care vs. usual care	3 RCTs (n=281) 2 CTs (n=90+)	Meta-analysis of the three RCTs showed no difference in psychological well-being compared with usual care (calculated standardized mean difference, 0.01; 95% CI, -0.39 to 0.41). Models for integrating palliative care were not more effective than usual care for symptoms of anxiety.	Not graded
	Pain ^{68, 70, 71, 73-75}	Models for integrating palliative care vs. usual care	2 RCTs (n=277) 1 CT (n=90) 2 prospective cohort studies (n=102)	None of the differences were clinically meaningful. Models for integrating palliative care were not more effective than usual care for pain.	Not graded
	Dyspnea ^{68, 70, 71, 73-75}	Models for integrating palliative care vs. usual care	2 RCTs (n=278) 1 CT (n=90) 2 prospective cohort studies (n=88)	Results were not clinically meaningful. Models for integrating palliative care were not more effective than usual care for dyspnea.	Not graded
	Fatigue ^{68, 71, 73}	Models for integrating palliative care vs. usual care	1 RCT (n=248) 2 prospective cohort studies (n=88)	Primarily based on the larger RCT results, models for integrating palliative care may not be more effective than usual care for fatigue.	Not graded
	Concordance between patient preferences and care received ⁷⁸	Models for integrating palliative care vs. usual care	1 RCT (n=31)	We were unable to draw conclusions.	Not graded

Type	Outcome	Comparison	Number of Studies (N at Analysis)	Findings	Strength of Evidence
Caregiver-centered outcomes	Caregiver HRQOL ⁷⁹	Models for integrating palliative care vs. usual care	1 RCT (n=82)	Models for integrating palliative care and usual care may have little to no effect on caregiver HRQOL compared with usual care.	Not graded
	Caregiver symptoms of depression ^{67, 79}	Models for integrating palliative care vs. usual care	2 RCTs (n=228)	Differences were not clinically meaningful. Models for integrating palliative care were not more effective than usual care for symptoms of depression.	Not graded
	Caregiver symptoms of anxiety ^{67, 79}	Models for integrating palliative care vs. usual care	2 RCTs (n=228)	Differences were not clinically meaningful. Models for integrating palliative care were not more effective than usual care for symptoms of anxiety.	Not graded
	Caregiver psychological well-being ⁶⁷	Models for integrating palliative care vs. usual care	1 RCT (n=147)	There may be little to no difference in caregiver psychological well-being between models and usual care.	Not graded
	Caregiver burden, impact, or strain ^{67, 79}	Models for integrating palliative care vs. usual care	2 RCTs (n=229)	There may be little to no difference in caregiver burden, impact, or strain between models and usual care.	Not graded
Healthcare utilization	Use and length of hospice care ^{24, 25}	Multimodal interventions vs. usual care	1 CT (n=74)	We were unable to draw conclusions.	Not graded
	Hospitalizations ^{26, 71, 72, 74, 75, 77}	Multimodal interventions vs. usual care Models for integrating palliative care vs. usual care	1 RCT (n=525) 2 RCT (n=698) 2 CT (n=493)	Multimodal: Results of one large RCT suggest that multimodal interventions may have little to no effect on hospitalizations compared with usual care. Models: Models for integrating palliative care were not more effective than usual care for hospitalizations.	Not graded

p=0.03].⁷⁶ It is not clear whether this is a meaningful difference. In the second RCT, patient satisfaction was assessed with an unnamed scale.⁷⁰ There were no reported differences in satisfaction between groups at 6 months.

Assessing satisfaction using the Group Health Association of America Consumer Satisfaction Survey (score ranges from 20 to 100), the CT reported that the control group had a total satisfaction score of 72.4 compared with 70.1 in the intervention arm (p=0.26).^{74, 75}

Models may have little to no effect on improving compared to usual care (SOE: Low).

Multimodal Interventions

No studies evaluating multimodal interventions assessed patient satisfaction.

Health-Related Quality of Life

Models for Integrating Palliative Care

Six RCTs and two CTs, reported in nine articles, assessed the effect of models for integrating palliative care on HRQOL.^{67, 69-72, 74, 75, 77, 78}

Four of the RCTs assessed HRQOL with the Kansas City Cardiomyopathy Questionnaire (KCCQ), which is a 0- to 100-point scale, where a change of 5 points is potentially clinically meaningful. One used the Minnesota Living with HF Questionnaire (MLHFQ) (0- to 105-point scale) and another the Quality of Life in Alzheimer's Disease scale (QOL-AD) (13- to 52-point scale). Two RCTs also used the Functional Assessment of Chronic Illness Therapy – Palliative Care scale (FACIT-PAL) (0- to 184-point scale).

In a meta-analysis of 4 RCTs,^{67, 69, 70, 78} we found no difference in HRQOL in patients enrolled in a model for integrating palliative care compared with usual care (calculated standardized mean difference, 0.19; 95% CI, -0.03 to 0.41, I-squared=0.0%) (Figure 2, see also Appendix D for more detailed forest plot of HRQOL).

The two additional RCTs did not report either followup data or variability measurements, so we were unable to calculate a mean between-group difference. Each of these reported no clinically meaningful differences between groups, consistent with our meta-analysis. The first RCT reported a difference in the KCCQ of 2.6 (95% CI, -1.3 to 6.6) between groups at 6 months (p=0.19).⁷¹ The second RCT reported that, at 1 year, KCCQ scores had increased by 13.5 for both the control and intervention groups (p=0.97).⁷²

The results from the two CTs are also consistent with our meta-analysis results. In the first CT, at 12 months, the control group reported a total mean score on the Multidimensional Quality of Life Scale – Cancer version (0- to 100-point scale) of 67.7 compared with the intervention group mean score of 69.3 (p=0.43).⁷⁴ No variability was reported, so we were unable to calculate a mean between-group difference. The second CT assessed HRQOL with the McGill Quality of Life Questionnaire [usual care, mean (SD) 4.89 (1.14) and intervention, mean (SD) 5.03 (0.87), p>0.05].

Across different scales, the results reported from the meta-analysis and individual studies were consistently not statistically or clinically meaningful. Models for integrating palliative care did not improve HRQOL (SOE: Moderate).

Figure 2. Meta-analysis of the effects of models for integrating palliative care on improving health-related quality of life in patients with noncancer serious chronic illness compared with usual care

CI=confidence interval; KCCQ-12=Kansas City Cardiomyopathy Questionnaire-12 item; MLHFQ=Minnesota Living with Heart Failure Questionnaire; N=sample size; SMD=standardized mean difference; KCCQ=Kansas City Cardiomyopathy Questionnaire

*Rogers, 2017 et al.⁶⁹ standardized mean difference calculated using difference between baseline and outcome at 6 months.

†A higher standardized mean difference for quality of life outcomes favors the intervention model over usual care.

Multimodal Interventions

No studies evaluating multimodal interventions assessed HRQOL.

Overall Symptom Burden

Models for Integrating Palliative Care

Two RCTs assessed the effect of models for integrating palliative care on overall symptom burden^{67, 71}. One study assessed the effect of a shared care model on heart failure patients over a period of 6 months. Symptom burden was described using the General Symptom Distress Scale (GSDS) (0- to 10-point scale)⁷¹. At 6 months, the reported mean between-group difference was 0.1 (95% CI, -0.5 to 0.7, p=0.8).

The second RCT assessed the effect of a model on patients with Parkinson's disease and related disorders over a period of 12 months. Symptom burden was assessed using the Edmonton Symptom Assessment Scale – Parkinson's Disease (ESAS-PD) overall score (0- to 140-point scale). At 12 months, the reported mean between group difference was -8.27 (95% CI, -13.9 to -2.6, p=0.004).

Given inconsistent results that are likely not clinically meaningful, models for integrating palliative care may have little to no effect compared with usual care for overall symptom burden (SOE: Low).

Multimodal Interventions

No studies evaluating multimodal interventions assessed overall symptom burden.

Symptoms of Depression

Models for Integrating Palliative Care

Six RCTs, one CT and two prospective cohort studies, reported in ten articles, assessed the effect of models for integrating palliative care on depression.^{67-75, 78} Depression was assessed using a wide variety of scales.

In a meta-analysis of three RCTs,^{67, 70, 78} we found no difference in symptoms of depression in patients enrolled in a model for integrating palliative care compared with usual care (calculated standardized mean difference, -0.09; 95% CI, -0.35 to 0.17, I-squared=0.0%) (Figure 3).

Three RCTs, one CT and two prospective cohort studies could not be included in the meta-analysis owing to missing baseline and/or variability data. Two of these RCTs assessed depression with the Patient Health Questionnaire-9 (PHQ9) (0- to 27-point range). The first RCT reported a difference of -1.4 (95% CI, -2.6 to -0.2) between groups ($p=0.02$).⁷¹ The other RCT reported a difference of 2.1 (95% CI, 0.43 to 3.78) between groups ($p=0.01$).⁷² Although these results were statistically significantly different, neither was clinically meaningful.

The third RCT assessed the impact of a shared care model on depression using the Hospital Anxiety and Depression Scale (HADS) (0- to 21-point scale) and reported a difference of -1.94 (95% CI, 3.57 to -0.31) between groups ($p=0.02$) that was clinically significant.⁶⁹

The two prospective cohort studies assessed depression with the Edmonton Symptom Assessment Scale (ESAS) (a 10-point scale). One cohort reported a change from a mean of 0.96 +/- 1.99 at baseline to 0.87 +/- 2.29 ($p=0.7$) at 6 months.⁷³ The other cohort reported a mean change (SD) of 2.65 (3.19) to 2.7 (2.74) (no statistics reported).⁶⁸ Neither result was clinically meaningful.

The CT evaluated the impact of a shared care model on depressive symptoms with the Center for Epidemiological Studies Depression Scale (0- to 60-point scale). At 12 months, the control group reported a score of 15.3 compared with 12.4 in the intervention arm ($p=0.28$).^{74, 75}

Given consistent results with the meta-analysis and additional studies, models for integrating palliative care were not more effective than usual care for depressive symptom scores (SOE: Moderate).

Figure 3. Meta-analysis of the effects of models for integrating palliative care on improving depressive symptom scores in patients with noncancer serious chronic illness compared with usual care

CI=confidence interval; HADS= Hospital Anxiety and Depression Scale; N=sample size; PHQ-8=Patient Health Questionnaire depression scale-eight item; SMD=standardized mean difference

Multimodal Interventions

No studies evaluating multimodal interventions assessed symptoms of depression.

Anxiety Symptom Scores

Models for Integrating Palliative Care

Five RCTs, one CT and two prospective cohort studies assessed the effect of models for integrating palliative care on anxiety.^{67-71, 73-75, 78}

Four RCTs assessed the impact of models for integrating palliative care on heart failure patients over a period of 6 months, and the fifth evaluated the impact of integrating palliative care on patients with Parkinson's disease and related disorders, also over a period of 6 months. In a meta-analysis of three RCTs,^{67, 70, 78} we found no difference in anxiety symptoms for patients enrolled in a model for integrating palliative care compared with usual care (calculated standardized mean difference, 0.06; 95% CI, -0.2 to 0.32, I-squared=0%) (Appendix D).

Two RCTs, one CT, and two prospective cohort studies could not be included in the meta-analysis owing to missing baseline and/or variability data. The first RCT assessed the impact of a consultative care model on anxiety using the Generalized Anxiety Disorder-7 (GAD-7) scale (0- to 21-point scale) and reported a difference of -0.9 (95% CI, -2 to 0.13) between groups at 6 months (p=0.09) that was not clinically meaningful.⁷¹ The second RCT assessed the impact of a shared care model on anxiety using the HADS and reported a difference of -1.83 (95% CI, -3.46 to -0.02) between groups at 6 months (p=0.048) that was clinically significant.⁶⁹

Both prospective cohort studies assessed anxiety with the ESAS (a 10-point scale). In one cohort, anxiety changed from a mean of 0.98 +/- 1.82 at baseline to 1.08 +/- 2.86 (p=0.8).⁷³ In the other cohort, anxiety changed from a mean (SD) of 1.65 (2.47) to 1.94 (2.5) (no statistics reported).⁶⁸ Neither was clinically meaningful.

The CT assessed anxiety using the Profile of Mood States and reported a score of 5.9 in the control group compared with 5.3 in the intervention arm ($p=0.68$).^{74, 75}

Any differences reported were not statistically significant or clinically meaningful, and our meta-analysis found no difference. Models for integrating palliative care were not more effective than usual care for anxiety symptom scores.

Multimodal Interventions

No studies evaluating multimodal interventions assessed anxiety symptom scores.

Psychological Well-Being

Models for Integrating Palliative Care

Three RCTs and two CTs, reported in six articles, assessed the effect of models for integrating palliative care on psychological well-being.^{67, 69, 74, 75, 77, 78}

Meta-analysis of the three RCTs showed no difference in psychological well-being compared with usual care (calculated standardized mean difference, 0.01; 95% CI, -0.39 to 0.41, I-squared=55.3%) (Appendix D).^{67, 69, 78}

The two CTs were not included in the analysis, because not enough information was available for calculations. Both reported results consistent with our meta-analysis. One CT assessed the impact of care coordinators on psychological well-being using the Functional Assessment of Chronic Illness Therapy–Spiritual Well-Being Scale (0- to 48-point scale). In that CT, the control group reported a mean (SD) score of 32.05 (10.53) compared with 34.43 (9.03) in the intervention arm ($p>0.05$). The second CT assessed the impact of a shared care model at 12 months using the Spiritual Well Being Scale (20- to 120-point scale). Patients in the intervention group reported a score of 105.5 compared with 92.4 in the control group ($p=0.007$). These differences were likely not clinically meaningful.

Models for integrating palliative care were not more effective than usual care in improving psychological well-being.

Multimodal Interventions

No studies evaluating multimodal interventions assessed psychological well-being.

Pain

Models for Integrating Palliative Care

Two RCTs, one CT, and two prospective cohort studies assessed the effect of models for integrating palliative care on pain.^{68, 70, 71, 73-75}

One RCT evaluated a consultative care model in patients with CHF over a period of 6 months.⁷¹ This RCT assessed pain with a composite outcome from the Brief Pain Inventory called PEG, for pain intensity (P), interference with enjoyment of life (E), and interference with general activity (G). At 6 months, there was a difference of 0.3 [95% CI -0.3 to 0.9; between groups ($p=0.35$)].

The second RCT also evaluated a model in patients with CHF over a period of 6 months.⁷⁰ This RCT assessed pain using the numeric rating scale from the Brief Pain Inventory and reported no differences between groups over the course of the study.

The CT evaluated a consultative care model including patients with COPD, CHF, and cancer and completing assessment at 12 months.^{74, 75} Assessing pain using the numeric rating scale of

the Brief Pain Inventory (BPI), the control group reported an average pain rating of 4.5 compared with 3.6 in the intervention arm ($p=0.41$).

One prospective cohort study evaluated a consultative model on a hemodialysis unit over a period of 6 months.⁷³ The other study evaluated the effect of a shared care model on a wider patient population over a time period ranging from 2 weeks to 9 months.⁶⁸ Both prospective cohort studies assessed pain with the ESAS (a 10-point scale). In one cohort study, pain changed from a mean of 1.34 \pm 2.39 at baseline to 2.04 \pm 2.47 ($p=0.04$).⁷³ In the other cohort study, pain changed from a mean (SD) of 3.59 (3.11) to 3.74 (2.57) (no statistics reported).⁶⁸

None of the differences reported in these studies was clinically meaningful. Models for integrating palliative care were not more effective than usual care for pain.

Multimodal Interventions

No studies evaluating multimodal interventions assessed pain.

Dyspnea

Models for Integrating Palliative Care

Two RCTs, one CT, and two prospective cohort studies assessed the effect of models for integrating palliative care on dyspnea.^{68, 70, 71, 73-75}

One RCT evaluated a consultative care model in patients with CHF over a period of 6 months.⁷¹ This trial assessed dyspnea using a numeric rating scale and reported a difference of 0.1 [95% CI, -0.5 to 0.7 between groups at 6 months ($p=0.76$)]. The second RCT also evaluated a model in patients with CHF over a period of 6 months.⁷⁰ This RCT assessed dyspnea using the Borg rating scale and reported no differences between groups over the course of the study.

The CT evaluated a consultative care model over a period of 12 months and included patients with COPD, CHF, and cancer.^{74, 75} This trial assessed dyspnea using the University of California, San Diego Shortness of Breath Questionnaire and, in contrast to the RCT, reported improvements in the intervention group. The odds of an intervention patient reporting any dyspnea were significantly less than usual care patients at 12 months (OR 6.07; 95% CI, 1.04 to 35.56). At 12 months, the degree to which dyspnea interfered (0 to 105) was reported as 40.6 in the control group compared with 25.4 in the intervention arm ($p=0.01$). At 12 months, the frequency at which dyspnea limited activities (0 to 18) was reported as 7.1 in the control group and 3.6 in the intervention arm ($p=0.07$).

One prospective cohort study evaluated a consultative model on a hemodialysis unit over a period of 6 months.⁷³ The other study evaluated the effect of a shared care model on a wider patient population over a time period ranging from 2 weeks to 9 months.⁶⁸ Both prospective cohort studies assessed dyspnea with the ESAS and each worsened with the intervention, although this was not clinically significant. In one cohort study, dyspnea changed from a mean of 0.34 \pm 1.06 at baseline to 1.06 \pm 1.95 ($p=0.009$).⁷³ In the other cohort study, dyspnea changed from a mean (SD) of 1.57 (2.63) to 1.75 (2.24).⁶⁸

Since results were not clinically meaningful, we concluded that models for integrating palliative care were not more effective than usual care for dyspnea.

Multimodal Interventions

No studies evaluating multimodal interventions assessed dyspnea.

Fatigue

Models for Integrating Palliative Care

One RCT and two prospective cohort studies assessed the effect of models for integrating palliative care on fatigue.^{68, 71, 73}

The RCT evaluated a consultative care model over a period of 6 months in patients with CHF.⁷¹ One prospective cohort study evaluated a consultative model on a hemodialysis unit over a period of 6 months.⁷³ The other study evaluated the effect of a shared care model on a wider patient population over a time period ranging from 2 weeks to 9 months.⁶⁸

The RCT assessed fatigue with the Patient-Reported Outcomes Measurement Information System Short Form 8a. There was a difference of -2 (95% CI, -3.6 to -0.4) between groups at 6 months (p=0.02), which is not clinically meaningful.

Both prospective cohort studies assessed fatigue with the ESAS, reporting inconsistent results. In one cohort, fatigue changed from a mean of 2.98 +/- 3.22 at baseline to 4.06 +/- 2.69 (p=0.02).⁷³ In the other cohort, fatigue changed from a mean (SD) of 5.49 (3.16) to 4.98 (2.52).⁶⁸

Given that differences were not clinically meaningful, models for integrating palliative care were not more effective than usual care for fatigue.

Multimodal Interventions

No studies evaluating multimodal interventions assessed fatigue.

Concordance Between Patient Preferences and Care Received

Models for Integrating Palliative Care

One RCT assessed the effect of integrating social workers in a heart failure population on concordance between patient preferences and care received over a period of 6 months.⁷⁸

Concordance was assessed as the percentage of patients with improvement in prognostic alignment. This was defined as the revision of patient expectations of prognosis in a direction consistent with those of the treating physician. At 6 months, 26 percent of the usual care arm, compared with 94 percent of the intervention arm, had prognostic alignment (p<0.001).

We were unable to draw conclusions about the effect of models for integrating palliative care on concordance between patient preferences and care received, because there was only one small study with high risk of bias.

Multimodal Interventions

No studies evaluating multimodal interventions assessed concordance between patient preferences and care received.

Caregiver-Reported Outcomes

Health-Related Quality of Life

Models for Integrating Palliative Care

One RCT assessed the impact of models for integrating palliative care on caregiver quality of life.⁷⁹ This RCT assessed a telehealth intervention on caregivers of patients with heart failure over a period of 16 weeks. Quality of life was assessed with the Bakas Caregiver Outcomes

Scale (scores range from 15 to 105). The reported mean between-group difference at 16 weeks was -0.4 (95% CI, -5.1 to 4.3, $p=0.88$). This was unlikely to be clinically meaningful.

There may be little to no effect of models for integrating palliative care compared with usual care on caregiver quality of life.

Multimodal Interventions

No studies evaluating multimodal interventions assessed HRQOL in caregivers.

Symptoms of Depression

Models for Integrating Palliative Care

Two RCTs assessed the impact of models for integrating palliative care on caregiver symptoms of depression.^{67, 79} The first RCT assessed a telehealth intervention on caregivers of patients with heart failure over a period of 16 weeks.⁷⁹ Symptoms of depression were assessed with the HADS. At 16 weeks, the reported mean between-group difference was 0.1 (standard error [SE], 0.5, $p=0.86$).

The second RCT assessed a model on caregivers and patients with Parkinson's disease and related disorders over a period of 6 months.⁶⁷ Symptoms of depression was also assessed with the HADS-depression scale. At 6 months, the reported mean difference was -0.9 (95% CI, -1.83 to 0.03, $p=0.06$).

Differences were not clinically meaningful, suggesting that models for integrating palliative care were not more effective than usual care for symptoms of depression.

Multimodal Interventions

No studies evaluating multimodal interventions assessed symptoms of depression in caregivers.

Symptoms of Anxiety

Models for Integrating Palliative Care

Two RCTs assessed the impact of models for integrating palliative care on caregiver symptoms of anxiety.^{67, 79} The first RCT assessed a telehealth intervention on caregivers of patients with heart failure over a period of 16 weeks.⁷⁹ Symptoms of anxiety were assessed with the HADS. At 16 weeks, the reported mean between-group difference was -0.1 (SE, 0.5, $p=0.88$).

The second RCT assessed a model on caregivers and patients with Parkinson's disease and related disorders over a period of 6 months.⁶⁷ Symptoms of anxiety was also assessed with the HADS-anxiety scale. At 6 months, the reported mean difference was -0.43 (95% CI, -1.46 to 0.61, $p=0.42$).

Differences were not clinically meaningful, suggesting that models for integrating palliative care were not more effective than usual care for caregiver symptoms of anxiety.

Multimodal Interventions

No studies evaluating multimodal interventions assessed anxiety symptoms in caregivers.

Psychological Well-Being

Models for Integrating Palliative Care

One RCT assessed the impact of models for integrating palliative care on caregiver psychological well-being.⁶⁷ This RCT assessed a model on caregivers and patients with Parkinson's disease and related disorders over a period of 6 months. Psychological well-being was assessed with the Functional Assessment of Chronic Illness Therapy–Spiritual Well-Being Scale. At 6 months, the reported mean difference between groups was 1.79 (95% CI, -0.0 to 3.6, $p=0.05$).

There may be little to no difference in the effect of models for integrating palliative care on caregiver psychological well-being.

Multimodal Interventions

No studies evaluating multimodal interventions assessed psychological well-being in caregivers.

Burden, Impact, or Strain

Models for Integrating Palliative Care

Two RCTs assessed the impact of models for integrating palliative care on caregiver burden, impact, or strain.^{67, 79} The first RCT assessed a telehealth intervention on caregivers of patients with heart failure over a period of 16 weeks.⁷⁹ Caregiver burden was assessed with the Montgomery-Borgatta Caregiving Burden Scale, broken down into 3 scales (objective, demand, and stress burdens). At 16 weeks, the reported mean between-group difference for the objective burden was 0 (SE, 0.5), $p>0.99$, for the demand burden -0.4 (SE, 0.4, $p=0.35$) and for the stress burden -0.4 (SE, 0.4, $p=0.38$).

The second RCT assessed a model on caregivers and patients with Parkinson's disease and related disorders over a period of 6 months.⁶⁷ Caregiver burden was assessed with the Zarit Burden Interview (ZBI-12). At 6 months, the reported mean difference -2.6 (95% CI, -4.58 to -0.61, $p=0.01$). We were unable to determine if this was clinically meaningful.

There may be little to no difference in the effect of models for integrating palliative care on caregiver burden, impact or strain.

Multimodal Interventions

No studies evaluating multimodal interventions assessed caregiver burden, impact, or strain.

Healthcare Utilization

Use and Length of Hospice Care

Models for Integrating Palliative Care

No studies evaluating models assessed use and length of hospice care.

Multimodal Interventions

One CT, reported in two articles, assessed the effect of multimodal interventions on use and length of hospice care.^{24, 25} The study evaluated use and length of hospice care among a subset of deceased patients with completed Medicare claims data whom had identified as being at high

risk. The percentage of patients with at least one day in hospice was 55.3 percent in the intervention arm compared with 40.7 percent in the usual care arm [relative risk (RR) 1.36; 95% CI, 0.81 to 2.29; $p=0.33$]. Length of hospice stay was not statistically different between groups (51 vs. 29.3 days, $p=0.43$).

We were unable to draw conclusions about the effectiveness of multimodal interventions on use and length of hospice care, as only one study reported inconclusive results.

Hospitalizations

Models for Integrating Palliative Care

Four studies, reported in five articles, evaluated the effect of models for integrating palliative care on hospitalizations.^{71, 72, 74, 75, 77} One study evaluated the effect of a model for integrating palliative care on rehospitalizations.⁶⁹

Two RCTs evaluated the effect of a model for integrating palliative care on hospitalization.^{71, 72} The first RCT evaluated clinician training/education combined with an integrated model of a nurse, social worker, palliative care specialist, and cardiologist providing symptom and psychosocial assessments compared with usual care over a period of 6 months in patients with CHF. There were no significant changes in the number of all-cause hospitalizations between the intervention group and the usual care group ($p=0.61$). The study reported individuals with one hospitalization and individuals with two or more hospitalizations. Among those with one hospitalization, 18 were in the intervention group and 30 were in the control group (RR 0.6; 95% CI, 0.35 to 1.03). Among those with two or more hospitalizations, 9 were in the intervention group and 6 were in the control group (RR 1.5; 95% CI, 0.55 to 4.11).⁷¹

The second RCT evaluated a collaborative care model of a nurse, primary care physician, cardiologist, and psychiatrist using home telemonitoring and patient self-management support in a heart failure population. The one-year hospitalization rates between the intervention group and the usual care group was similar between groups (29.4% vs. 29.9%, $p=0.87$).⁷²

One CT, reported in two articles, evaluated patient-caregiver training/education combined with an integrated model of a social worker, nurse, chaplain, pharmacist, psychologist, art therapist, volunteer coordinator, and three physicians compared with usual care over a period of 12 months in patients with COPD, CHF, and cancer. The mean number of hospitalizations during 12 months (1.2 vs. 0.8, $p=0.21$) and the mean number of hospitalized days (6.3 vs. 4.3, $p=0.38$) was not different for the intervention group compared with the usual care group.^{74, 75}

One CT consisted of a 6-session intervention delivered by social workers or health educators focused on health counseling, education, and care coordination in patients with CHF, COPD, cancer, or end-stage renal disease. In the prospective trial, inpatient admissions in the intervention group and control group at post-test, respectively, were 4.33 (SD 16.26) vs. 2.44 (SD 5.11, $p=0.045$).⁷⁷

One RCT, evaluating the integration of a palliative care nurse practitioner supported by a palliative care physician into the care of heart failure patients, reported rehospitalization.⁶⁹ Compared with patients in the usual care group, the number of patients in the intervention group with a six-month rehospitalization rate for heart failure (30.7% vs. 29.3%, RR 1.05; 95% CI, 0.64 to 1.7), non-heart failure cardiovascular (16% vs. 10%, RR 1.2; 95% CI, 0.55 to 2.61), and non-cardiovascular (10.7% vs. 24%, RR 0.44; 95% CI, 0.21 to 0.96) did not differ from the usual care group.⁶⁹

We were unable to conduct a meta-analysis, as two RCTs were missing either followup data or variability measurements. Models for integrating palliative care were not more effective than usual care for the outcome of hospitalizations.

Multimodal Interventions

One RCT assessed the effect of multimodal intervention on hospitalization.²⁶ The RCT evaluated a clinician training/education combined with an automatic trigger to initiate implantable cardioverter-defibrillators deactivation discussion among advanced heart failure patients (n=525). The mean number of hospital admissions within 24 months of study enrollment did not vary between intervention and control group (1.4 vs. 1.2, p=0.13).²⁶

Our confidence is limited by only one study reporting this outcome, but results suggest that multimodal interventions had little to no effect on hospitalizations.

Advance Directive Documentation

Models for Integrating Palliative Care

Seven studies, reported in eight articles, evaluated the effect of models for integrating palliative care on advance directive documentation.^{67, 70, 73-78}

Four RCTs evaluated the effect of models for integrating palliative care on advance directive documentation.^{67, 70, 76, 78} The first RCT evaluated a social work integration model where social workers led patients through structured goals-of-care conversations over a period of 6 months (n=50). Advance directive documentation was reported as two different outcomes: percent of patients with any documentation of advance care preferences in electronic health records prior to death and percent of patients with physician-level documentation of advance preference that included hospice referral or end-of-life care.⁷⁸ The second RCT evaluated a six-session intervention focused on care coordination, physician support, health literacy, and end-of-life planning over a period of 6 months in patients with COPD, CHF, and cancer.⁷⁶ The third RCT evaluated a five-month intervention where palliative care consultation was provided by an interdisciplinary team of nurse practitioner, physician, social worker, and chaplain to patients with heart failure who were recruited during hospitalization.⁷⁰ The last RCT evaluated a year-long integrated outpatient palliative care delivered by a neurologist, social worker, chaplain, nurse, and palliative medicine specialist to patients with Parkinson's disease and related disorders every 3 months.⁶⁷

We conducted a meta-analysis with all four RCTs using percent completion of advance directive (AD) documentation at 6 months. All studies provided group differences. Based on the overall pooled results from the meta-analysis, patients in the intervention group had a 62.0 percent statistically higher chance of having AD documentation compared with patients in standard care (Relative Risk, 1.620 CI, 1.350 to 1.945, I-squared=0.0%) (Figure 4).

Two CTs, reported in three articles, evaluated the effect of models for integrating palliative care on AD documentation.^{74, 75, 77} The first CT evaluated patient-caregiver training/education combined with an integrated model of a social worker, nurse, chaplain, pharmacist, psychologist, art therapist, volunteer coordinator, and three physicians compared with usual care over a period of 12 months in patients with COPD, CHF, and cancer.^{74, 75} Advance directive documentation was reported as percent of patients with Durable Power of Attorney for Health Care (DPOA-HC)

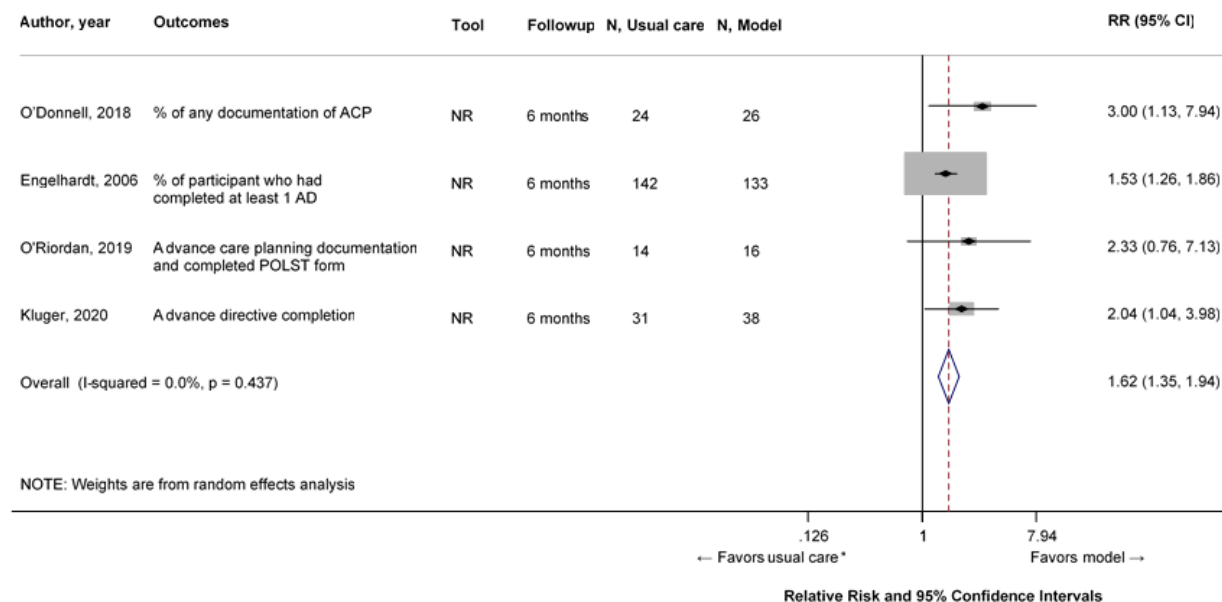

paperwork completed. The percent of patients completing DPOA-HC paperwork was 40 percent for the intervention and 38 percent for the control group (RR 1.92; 95% CI, 0.74 to 5; $p=0.91$).

The second CT consisted of a six-session intervention delivered by social workers or health educators focused on health counseling, education, and care coordination in patients with CHF, COPD, cancer, or end-stage renal disease.⁷⁷ Advance directives were reported as the patient's formulation of ADs, including the designation of a proxy or living will, and the days to formulation of advance care directives. Patients in the intervention group were 2.22 times (95% CI, 1.62 to 3.05) more likely to formulate an AD compared with the usual care group (47% vs. 21%, $p<0.05$).

One prospective cohort study evaluated an embedded model of palliative care physician consultations on a hemodialysis unit.⁷³ Advance directive documentation was reported as advance directives in medical records. Advance directives increased from 41 percent preintervention to 46 percent postintervention ($p=0.22$) during the study period of 6 months.

Compared with the results of our meta-analysis, the results of the two CTs are consistent in reporting greater AD completion among patients in the intervention group compared with those in the usual care group, although the results are not statistically significant. Based on the results of our meta-analysis and consistent results from additional studies, we concluded that models for integrating palliative care were more effective than usual care for increasing advance directives documentation (SOE: Moderate).

Figure 4. Meta-analysis of the effects of models for integrating palliative care on increasing advance directive documentation in patients with noncancer serious chronic illness compared with usual care

ACP=advanced care planning; AD=advanced directive; CI=confidence interval; N=sample size; POLST=Portable Medical Orders; RR=relative risk; SMD=standardized mean difference

*Relative risk over 1 for advance directive outcomes favors the intervention model over usual care.

Multimodal Interventions

One RCT evaluated a clinician training/education combined with an automatic trigger to initiate implantable cardioverter-defibrillators deactivation discussion among advanced heart failure patients.²⁶ Advance directive documentation was assessed as the percent of chart documentation of advance directives, including healthcare proxy, living will, or do-not-resuscitate orders. Compared with the usual care group, those receiving the intervention did not have notable differences in the percent of chart documentation of advance directives (57.9% vs. 52.6%, $p=0.37$). This outcome is considered indirect as is an intermediate, non-patient reported outcome, but it was reported in a large trial with low risk of bias. Multimodal interventions may have little to no effect on advance directive documentation (SOE: Low).

Costs and Resource Use

Models for Integrating Palliative Care

Three CTs and one prospective cohort study, reported in five articles, assessed the effect of models for integrating palliative care on costs and resource use.^{68, 74-77}

In the first CT, costs were reported as mean charges per patient for medical center services that include clinic visits, urgent care visits, emergency department (ED) visits, and hospital stay. These charge data were obtained from computerized billing records. The mean charge per patient for all medical center services for the intervention group was \$47,211 (SD, \$73,009) for intervention patients and \$43,338 (SD, \$69,647) for the usual care group ($p>0.05$).^{74, 75}

In the same CT, resource use tabulated visits to general medicine clinics, specialty clinics, urgent care clinics, and the ED. The mean number of general medicine clinic visits was 3.1 points less for patients in the intervention group compared with those in the usual care group (7.5 vs. 10.6, $p=0.03$). The mean number of urgent care clinic visits for patients in the intervention group was half the number compared with those in the usual care group (0.3 vs. 0.6, $p=0.03$).^{74, 75}

In the second CT, costs were assessed at the patient-level six months prior to enrollment and at 3 months and 6 months post enrollment, and abstracted from the Veterans Affairs (VA) medical center database. Costs included direct healthcare costs associated with inpatient and outpatient care, stays in nursing home, and inpatient hospice, in addition to ancillary costs of diagnostic services, medication, durable medical prosthetics, care provided in non-VA settings, and administrative overhead, including salary (i.e., described as also including the cost of the intervention, although details were not specified). At 6 months post-enrollment, the mean cost per patient in the intervention group was \$12,123 (SD \$16,036) and the mean cost per patient in usual care group was \$16,295 (SD \$28,492). The difference in mean costs between the groups was \$4,172 (SD \$12,456) ($p=0.29$) (mean between group difference [MBGD] -3424.42, 95% CI, -13519.98 to 6671.14). The study did not report resource use.⁷⁶

In the third CT, costs were not reported. Resource use tabulated mean number of hospital stays, ED visits, home health visits, outpatient visits, radiology tests, laboratory tests, and medication. Compared with the usual care group, patients in the intervention group had 2.59 more outpatient visits [32.01 (SD 25.05) vs. 29.42 (SD 25.52), analysis of variance (ANOVA) $F=1.40$]. Compared with the usual care group, patients in the intervention group had 1.66 fewer ED visits [3.69 (SD 6.14) vs. 5.35 (SD 12.87), ANOVA $F=3.60$]. Adjusting for baseline variables, age, and sex, the post-test difference between the number of medical services used between the intervention group and the usual care group was not significant.⁷⁷

The prospective cohort study only reported resource use as mean ED visits per week in the year 2009 (baseline) and 2010 (enrollment period).⁶⁸ The mean ED visits per week decreased significantly between 2009 (0.07 visits) and 2010 (0.04 visits) after enrollment ($p=0.001$).

Models for integrating palliative care report different metrics to assess costs and resource use and this makes it difficult to compare results. Charge data using patient bills serve as a proxy for costs and are not reflective of actual costs incurred by the patient in the CT.⁷⁴ Costs reported in the RCT do not capture long-term evaluation and varying outcomes associated with diagnosis that impact differences between the intervention group and the usual care group.⁷⁶ Reporting metrics for resource use was also inconsistent in terms of type of health services used and frequency of use to draw meaningful conclusions.^{74, 75, 87} Studies varied widely in reporting metrics of outcomes related to cost and resource use and did not generally report intervention costs and, as such, we were not able to draw conclusions about the effect of models for integrating palliative care versus usual care on cost and resource use.

Multimodal Interventions

One CT, reported in three articles, assessed the effect of multimodal interventions on cost and resource use.^{24, 25, 86}

The study evaluated the Serious Illness Care program, a communication intervention, on total monthly medical expense using claims data among two cohorts of deceased patients: 1) those in intervention and comparison clinics, regardless of conversation status and 2) those in the intervention clinics with and without conversation.⁸⁶ The study did not account for the costs of the intervention. Comparing those in intervention to comparison clinics, total monthly medical expenses were not statistically significantly different at baseline, seven to twelve months before death, (baseline: \$4,006 vs \$4476, $p=0.67$) and at last six, three, and one month of life (last six month: \$7,345 vs \$8,867, $p=0.16$; last three months: \$8,994 vs \$10,504, $p=0.45$ last one month: \$12,602 vs \$13,563, $p=0.77$). These differences may be clinically meaningful, but cost data was incomplete. We conclude that multimodal intervention may have little to no effect on cost and resource use compared with usual care.

Adverse Effects

Medication Side Effects

No studies of models for integrating palliative care or multimodal interventions reported medication side effects.

Dropouts Related to the Intervention

No studies of models for integrating palliative care or multimodal interventions reported dropouts related to the intervention.

Key Subquestion c. How Have They Been Implemented?

Key Question 1c. How have prediction models, tools, and triggers for identifying when and which patients with serious life-threatening chronic illness or conditions in ambulatory settings could benefit from palliative care been implemented? What is the evidence for how, when, and for which patients they could best be implemented in care?

We identified no studies for this Key Question.

Key Question 2c. How have educational materials and resources about palliative care and palliative care options for patients with serious life-threatening chronic illness or conditions and their caregivers in ambulatory settings been implemented? What is the evidence for how, when, and for which patients and caregivers they could best be implemented in care?

We identified no studies for this Key Question.

Key Question 3c. How have palliative care shared decision-making tools been implemented for patients with serious life-threatening chronic illness or conditions in ambulatory settings and their caregivers? What is the evidence for how, when, and for which patients and caregivers they could best be implemented in care?

Key Points

How have they been implemented?

- Shared decision-making tools evaluated for implementation all focused on advance care planning.
- Studies addressed heart failure, ESRD, and COPD populations.

How could they best be implemented in care?

- Patients and caregivers preferred advance care planning discussions grounded in patient and caregiver experiences of illness, rather than general conversations about the end of life.
- Clinicians preferred advance care planning shared decision-making tools that were time-efficient and included structured scripting.

When could they best be implemented?

- Patients and caregivers felt that timing of advance care planning conversations should be individualized to the specific patient and caregiver.

Description of Included Studies

We identified five studies that used different approaches to explore how, when, and for which patients palliative care shared decision-making tools could best be implemented. These studies primarily described the implementation of tools or interventions that facilitated advance care planning discussions,⁵⁰⁻⁵² how clinicians document these discussions,⁸⁸ and systematic efforts to promote interdisciplinary collaboration among diverse treating

providers (Table 18).⁸⁹ The studies included patients (2 studies, n=18),^{50, 51} caregivers (2 studies, n=38, such as family members),^{51, 52} and nonpalliative care ambulatory clinicians (physicians and nurse practitioners) (3 studies, n=47).^{50, 88, 89} One study conducted qualitative observations⁵⁰ and four studies conducted qualitative interviews^{51, 52, 88, 89} (see Appendix D for full study characteristics).

Shared decision-making tools were considered related to the following conditions: COPD (1 study),⁵⁰ general populations with serious illnesses (1 study),⁸⁸ advanced heart failure [with Left Ventricular Assist Devices (LVADs)] (1 study),⁵¹ and end-stage renal disease (ESRD) on dialysis (2 studies).^{52, 89} One ESRD study was linked to a quantitative effectiveness evaluation of the intervention.⁵² Two studies were rated as low quality because the overall research methodology, analysis of data, and interpretation of results were insufficiently described.^{50, 89} The remaining three studies were classified as high quality.^{51, 52, 88} All studies used thematic analysis. Although one study reported “grounded theory” as their analytic technique, this may be more appropriately described as thematic analysis, because the authors conducted analyses for the development of themes.⁸⁹ (see Results Appendix D for study details).

Table 18. Characteristics of qualitative studies for shared decision-making tools

Author, Year	Study and Participant Characteristics and Funding	Intervention Description
Dillon, 2017 ⁸⁸	n=13 <ul style="list-style-type: none"> Clinicians, single-center, outpatient multispecialty group practice Cardiology, pulmonology, oncology, and primary care clinicians Multiple funding sources 	No intervention evaluated. (Study described the process of how clinicians currently incorporate documentation of advance care planning into the electronic health record.)
Uhler, 2015 ⁵⁰	n=12 (4 patients, 8 physicians) <ul style="list-style-type: none"> Multi-site, outpatient pulmonary clinic and outpatient pulmonary rehab Pulmonologists and patients with chronic obstructive pulmonary disease (COPD) Government funding 	The Informed Together decision aid is a Web-based platform that projects survival outcomes using patient age and disease severity that can be entered by a patient or clinician. After the information is entered, several pages are produced, including personalized survival estimates for Full Code vs. Do Not Resuscitate (DNR) advanced directive status and a suggested script to discuss the topics of prognosis and planning in case of a COPD exacerbation.
Metzger, 2016 ⁵¹	n= 28 (14 patients, 14 caregivers) <ul style="list-style-type: none"> Single-center, outpatient Left Ventricular Assist Device (LVAD) clinic LVAD patients and caregivers Multiple funding sources 	Advance Care Planning Intervention: Usual care with SPIRIT-HF intervention: one-hour, structured discussion facilitated by a Ph.D.-prepared nurse, trained in the original SPIRIT intervention, with patients with LVADs and their designated caregiver decision-makers. Discussion aimed to elicit patient and caregiver understanding of the patient's heart failure, the LVAD, prognosis, and life-sustaining treatment. Using this understanding, the nurse facilitated discussion between patient and caregiver regarding different end-of-life scenarios.
Song, 2017 ⁵²	n=24 <ul style="list-style-type: none"> Multi-site, outpatient dialysis clinics Bereaved caregivers of dialysis patients Government funding 	Advance Care Planning Intervention: the SPIRIT intervention included two sessions delivered by a trained nurse. The nurse assessed cognitive, emotional, and spiritual/religious aspects of patient and caregiver understanding of the patient's illness, prognosis, and end-of-life care. The nurse used this information to provide individualized information about effectiveness of life-sustaining treatment for people on dialysis, helping the patient examine their own values about life sustaining treatment, and facilitated a discussion between the patient and caregiver to prepare the caregiver for decision-making.
O'Hare, 2016 ⁸⁹	n=26 providers <ul style="list-style-type: none"> Multi-site, Veterans Affairs Healthcare System Cardiology, Geriatrics, Intensive Care, Nephrology, Palliative Care, Physiatry, Primary Care, Social Work, Vascular Surgery, Nutrition Government funding 	<ul style="list-style-type: none"> No intervention evaluated. Table 19. Integrative review results on qualitative evidence for how, when, and for which patients and caregivers shared decision-making tools could best be implemented in care

Factors for Implementation of Shared Decision-Making Tools	Clinician/Stakeholder and Patient/Caregiver Perceptions
External factors	Not addressed
Organizational factors	Concerns about implementation during routine care owing to time constraints
Organizational characteristics	Not addressed
Collaboration, resources and leadership	Not addressed
Intervention and implementation characteristics	<p><u>Intervention:</u></p> <ul style="list-style-type: none"> • Preferences for grounding in patient and caregiver experiences of illness, rather than general conversations about the end of life* • Providing information about the life-limiting nature of the illness* • Acknowledge the caregiver's role and empower and prepare them and open communication with patient* • Patients/caregivers: individualize timing to preferences*; clinicians: at time of medical stability • Should be time-efficient, specific, and succinct <p><u>Implementation:</u></p> <ul style="list-style-type: none"> • Integration into clinical workflow • Need for standardized workflows
Clinician/team characteristics	<ul style="list-style-type: none"> • Advance care planning should be conducted by clinician who knows the patient best • Systematic efforts to promote interdisciplinary collaboration among diverse clinicians
Patient/caregiver characteristics	Not addressed

The studies we identified evaluated the implementation of advance care planning tools alongside clinical workflows and assessed overall patient, caregiver, and clinician experiences of advance care planning experiences (Table 19). Two studies discussed clinicians' perspectives on incorporating advance care planning into their clinical processes and in interactions with patients to improve the delivery of care.^{88, 89} Two studies evaluated iterations of the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) intervention, a nurse-led intervention consisting of nurse-facilitated discussions with patients and their caregivers regarding various advance care planning topics.^{51, 52} SPIRIT-HF adapted the original SPIRIT intervention targeting dialysis patients and caregivers for use among LVAD patients and caregivers. The remaining study examined the acceptability of a Web-based decision-making aid providing individualized survival estimates and suggested scripting to discuss advance care planning and prognosis.⁵⁰

Below are findings from the patient, caregiver, and clinician perspectives as to how, when, and for which patients and caregivers shared decision-making tools could be implemented.

How. In terms of how shared decision-making tools should be implemented, patients and caregivers reported that sharing the story of their serious illness was a positive and essential part of the experience in the intervention, focusing the discussion on the patient's and caregiver's experiences, rather than starting by talking about death.⁵¹ Patients and caregivers who experienced SPIRIT or SPIRIT-HF felt that the intervention brought peace of mind by allowing them to express and clarify their wishes and ensuring that they were prepared for future care decisions.^{51, 52} Further, caregivers saw the SPIRIT intervention as an opportunity for discussion of topics that had previously been avoided (e.g., death, life-sustaining treatments, acceptable/unacceptable outcomes, end-of-life

preferences).⁵² In addition to perceived improvements in HRQOL among caregivers who received the intervention, caregivers also perceived that SPIRIT provided them with information about the life-limiting nature of the patient's illness, prompted them to consider circumstances in which life-sustaining treatments may/may not be beneficial, and acknowledged the caregiver's role in making decisions on behalf of the patient's wishes. Caregivers additionally reported that this empowered them and opened lines of communication with the patient, while also incorporating other family members into care decisions, resulting in caregivers feeling better prepared to make decisions during the time preceding end-of-life decision-making and taking into account their loved one's wishes.⁵² Clinician interviews highlighted the need for systematic and standardized workflows that support ACP discussions and documentation, including improving interdisciplinary collaboration between various providers caring for patients with serious illness.^{88, 89}

When. Several studies evaluated the best timing for the implementation of palliative care shared decision-making tools. In one study, patients and caregivers felt that advance care planning discussions should take an individualized approach and that the best timing may vary by person.⁵¹ Clinicians in this study felt that advance care planning conversations should be initiated during a time of medical stability, identified by the clinician who sees the patient most frequently; the clinician has a trusting relationship with the patient and should act as the “quarterback” who is responsible for advance care planning for that patient.⁵¹ Similarly, as described through the SPIRIT and SPIRIT-HF interventions, patients and caregivers recommended integration of the advance care planning discussion into the normal clinical workflow of the LVAD and dialysis clinics but did not detail when, how frequently, or by whom these discussions should be conducted and documented.⁵⁰ Clinicians identified the need for standardized workflows to incorporate discussions, such as those in the SPIRIT interventions, into routine care.⁵⁰ Overall, clinicians felt advance care planning tools are acceptable but should be time efficient, specific, and succinct, and also felt that clinician education would enhance successful implementation.^{50, 88}

For Which Patients. The studies we identified evaluated the implementation of palliative care shared decision-making tools during routine ambulatory clinical care for patients with COPD,⁵⁰ advanced or end-stage renal disease,^{52, 89} and advanced heart failure.⁵¹

Grounding advance care planning discussions in patient and caregiver experiences with their illness, rather than as a general discussion about death, was acceptable to patients and caregivers.^{51, 52} Patients and caregivers felt that the timing of these conversations should be individualized to specific patients and caregivers;⁵¹ some expressed a desire for initiation of these conversations earlier in the disease course.⁵¹ Clinicians found these tools acceptable when the tools were time efficient and included structured scripting, but they had concerns about implementation during routine ambulatory care owing to time constraints within the visits or lack of systematic implementation.^{50, 89}

KQ4c. How have palliative care training and educational materials (with or without other intervention components) for nonpalliative care clinicians caring for patients with serious life-threatening chronic illness or conditions in ambulatory settings been implemented? What is the evidence for how, when, and for which clinicians they could best be implemented in care?

Key Points

- Equipping clinicians to provide advance care planning training to their physician colleagues was perceived as acceptable.
- Clinicians reported that scripting advance care planning guides facilitated initiation of patient-centered conversations.

Description of Included Studies

We identified one study that evaluated clinicians' self-reported learning experiences following a clinician-led training course using the Serious Illness Conversation Guide.⁶⁴ This study used a "train-the-trainer" model, which consisted of training clinicians (n=22) within three large healthcare systems to subsequently train nonpalliative care clinicians (n=297) to use the Guide within their respective institutions (Table 20) (see Results Appendix D for full study characteristics). We judged this study as low quality because the overall research methodology, analysis of data, and interpretation of results were insufficiently described.

Table 20. Characteristics of qualitative studies for shared decision-making tools

Author, Year	Study and Participant Characteristics and Funding	Intervention Description
Paladino, et al., 2019 ⁶⁴	n=22 trainers, n=297 <ul style="list-style-type: none"> • Clinicians trained, multi-site, multiple specialties • Cardiology, radiation oncology, oncology, geriatrics, pediatrics, family medicine, primary care/internal medicine, palliative care, critical care/ICU, pulmonary, nephrology, other/unknown • Industry funding 	<ul style="list-style-type: none"> • Trainer Training: The two-day, train-the-trainer curriculum was based on best educational practices and adult learning theories, including attention to knowledge, attitudes, and skills-oriented practice with feedback. The goal was to prepare faculty trainers to deliver a predesigned, structured, 2.5- to 3-hour clinician training on serious illness communication. • Trainee Training: Led by the trained clinicians from within the respective institution, the clinician training teaches clinicians to have conversations about patients' values, goals, and prognoses using a scalable tool, the Serious Illness Conversation Guide. The training involved interactive methods, including reflection, demonstration and debriefing, cognitive maps, and skills practice with feedback.

ICU = intensive care unit.

When clinicians were equipped to provide training to their clinician colleagues within the same institution, they reported that they felt more comfortable initiating advance care planning discussions following the training. Clinicians reported that the scripting of the Serious Illness Guide allowed for easier initiation of conversations while facilitating efficient, natural, patient-centered conversations. Physicians, advanced practice clinicians, nurses, social workers, and chaplain trainers found this training model acceptable to use in their respective ambulatory practices.

KQ5c. What are components of models and multimodal interventions for integrating palliative care in ambulatory settings? What models and multimodal interventions have been implemented for key subpopulations? What components and characteristics of these models and multimodal interventions contribute to their effective implementation? What is the evidence for how, when, and for which patients they could best be implemented in care?

Key Points

What are components of models and multimodal interventions for integrating palliative care?

- Models for integrating palliative care and multimodal interventions evaluated for implementation included strategies to facilitate shared decision-making and communication to address symptoms and goals of care, designated roles and responsibilities for each team member, and structured workflows to promote integration and address followup care.

What has been implemented for key subpopulations?

- Models for integrating palliative care and multimodal interventions have been evaluated for implementation among patients with COPD, ESRD, and advanced heart failure, and in general primary care populations.

How could they best be implemented in care?

- Patients valued clinicians who understood the unique considerations of their illness trajectory in providing individualized care.
- Patients perceived cost of care, scheduling additional visits, and traveling to the clinic as key barriers to implementation.
- Clinicians preferred implementation with clear goals, objectives, and roles for each clinician involved, and accounting for the specific needs of key stakeholders.
- Clinicians perceived that implementation requires: 1) patient-centered needs assessments and performance measures, 2) collaboration among clinicians and local leaders, and 3) adequate financial support.

When could they best be implemented?

- Patient perceptions of appropriate timing to initiate palliative care varied, but patients did not have concerns about palliative care being initiated too early.

Description of Included Studies

We identified 10 studies investigating models for integrating palliative care and multimodal interventions in ambulatory settings from both patient and clinician perspectives (Table 21, Tables 22 and 23 reflect integrative review results on the qualitative evidence for components and characteristics of models for integrating palliative care in ambulatory settings and integrative review results on the qualitative evidence for how, when and for which patients models for integrating palliative care could best be implemented). These studies evaluated barriers and facilitators from both practical and implementation frameworks, in addition to the overall patient experience. Of the ten included studies, five were intervention studies: one study was a shared care model,⁸⁰ one study involved social workers in care delivery,⁸³ two studies used consultative

care models,^{81, 82} and one study was a multimodal intervention of clinician training/education with a trigger.⁸⁴

The studies included patients (5 studies, n=146),^{80-82, 90, 91} nonpalliative care ambulatory physicians (3 studies, n=51),^{84, 92, 93} and clinical team members on a palliative care advisory group (n=11).⁹⁴ One study⁸³ was conducted with clinicians, patients, and caregivers; however, the total number of people who answered open-ended questions was not reported. One study conducted qualitative observations and evaluated open-ended survey responses⁸³ and nine studies conducted individual qualitative interviews^{80-82, 84, 90-94} (see Results Appendix D for full study characteristics).

All studies used some variation of thematic analysis. One study reported “modified grounded theory,” which, on further examination, appeared to be better characterized as a thematic analysis.⁹⁰ and another study reported “constant comparison derived from grounded theory” for the development of themes.⁹¹ Seven of the ten articles were rated as high quality.^{80, 83, 84, 91-94} Three articles were rated as low quality because the overall research methodology, analysis of data, and interpretation of results were insufficiently described, thus we could not determine how well the conclusions were supported by the analysis and interpretation of the data.^{81, 82, 90}

Components of Models or Multimodal Interventions for Integrating Palliative Care in Ambulatory Settings

Four studies investigated the feasibility and acceptability of implementing different models: 1) Collaborative Care to Alleviate Symptoms and Adjust to Illness (CASA) among patients with COPD, advanced heart failure, and hypertension, to better integrate psychosocial and symptom-focused care into chronic care, using a shared care model,⁸⁰ 2) Comprehensive Care Team (CCT) intervention for outpatients actively pursuing treatment of advanced illness, which provided multiple palliative care consults for the primary care clinician in addition to advance care planning, psychosocial support, and family caregiver training for patients with a palliative care model,⁸² 3) an Advanced Practice Nurse (APN)-led intervention which included monthly visits by the APN and weekly phone-based symptom monitoring to assess and treat dyspnea, anxiety, and depression using “usual palliative care pharmacological and nonpharmacological interventions” guided by patient preferences using a consultative model,⁸¹ and 4) the Shared Decision-Making and Renal Supportive Care” (SDM-RSC), which involved social workers longitudinally with a focus on communication and advance care planning for patients with end-stage kidney disease on hemodialysis.⁸³ In addition, one study evaluated a multimodal intervention, the Serious Illness Care Program, among primary care clinicians (physicians, care coordination nurses, and social workers) to use workflow innovations, clinician training, and triggers to improve serious illness communication.⁸⁴

Components of Models for Integrating Palliative Care or Multimodal Interventions That Contribute to Effective Implementation

Patients

One study identified several simple and low-resource components of an intervention that were perceived to be useful and may be offered by non-medical personnel: 1) obtaining social services that patients already qualify for under existing funding mechanisms, 2) facilitating better communication about difficult issues, and 3) offering patients the simple gift of listening with compassion.⁸² In another study, patients indicated that they want to feel heard and be “seen,” to be instructed by a clinician who understands the context around their illness and its trajectory and who is able to offer solutions to individual concerns.⁹⁰ Patients and caregivers described the importance of programs involving family caregivers, focusing on helping patients and families adjust to both the limitations of and future of the illness, stressing the need to provide symptom relief that complements disease-specific strategies.⁹¹

The interventions delivered by Registered Nurses (RNs), APNs, or social workers were feasible and patients perceived them to be beneficial.^{80, 81, 91} Patients were satisfied with the phone structure of the intervention, perceiving such structure as generally helpful, although they

also noted that the symptom surveys were burdensome and repetitive.⁸⁰ Among interventions led by RNs or APNs, patients saw the as advocates.^{80, 81}

The studies also identified components of models that patients perceived to hinder implementation. In particular, COPD patients wanted questionnaires to be more specific to COPD conditions, wanted the intervention to be longer, and felt that there were “inappropriate” questions about sex and COPD.⁸¹ In another study, patients similarly commented on the structure of the survey, which they generally deemed as being burdensome and repetitive.⁸⁰ Patients identified a variety of barriers to participation, which included lack of clinician time; difficulty scheduling sessions within busy schedules; and driving to the clinic for study visits, which was recommended to correspond with regular clinic visits to ease the burden of travel.⁸¹ Additionally, patients’ concerns about both taking opioids and the cost of paying for pulmonary rehabilitation and palliative care clinic visits influenced their decision to continue palliative care after the close of the study.⁸¹

Clinicians

Studies identified four key components that contributed to clinicians’ perceptions of effective implementation of models for integrating palliative care: (1) clarifying the goals of collaborative care and creating a shared ownership,⁹⁴ (2) establishing clear professional roles and responsibilities,⁸⁴ (3) paying special attention to specific stakeholder needs and relationships,^{84, 94} and (4) clearly structuring interventions aiming to change the way our system drives serious illness communication.⁸⁴ In another study, however, clinicians noted that the development of a dedicated, interdisciplinary team of clinicians and volunteers is potentially beyond the capabilities of some healthcare institutions.⁸²

We summarized findings from the patient, caregiver, and clinician perspectives as to how, when, and for which patients and caregivers the models or multimodal interventions could be implemented.

How. From the clinician perspective, one study highlighted several key barriers and facilitators to implementation, noting that future efforts to scale up and implement the SDM-RSC intervention could benefit from additional ACP training for both social workers and nephrologists, including interprofessional training.⁸³ Another study described organizational factors that could influence the adoption and scale-up of outpatient palliative care in chronic advanced illness, using the example of heart failure.⁹³

To effectively adopt and scale outpatient palliative care, they identified the need to 1) develop performance measures for patient-centered care and outcomes, 2) justify any additional personnel costs, 3) communicate and coordinate with other clinicians, especially primary care practitioners (PCPs), 4) collaborate with local leaders to align palliative care with local programs, and 5) clarify the roles and responsibilities of outpatient palliative care versus primary and specialty care for disease management in advanced chronic illness. Clinicians described feeling hindered by the lack of community for palliative care (though they could refer to hospice), which could be aided by a patient registry, a multidimensional needs assessment, decision aids, and support for care management to facilitate palliative care; coaches were helpful for some clinicians, and study participants noted that palliative care needs to be financially supported and prioritized by practices. Clinicians perceived that attention to the multidimensional domains of basic palliative care may enable clinical practices to address the unmet needs of patients

with complex illnesses by using existing practice improvement models, strategies, and prioritization.⁹²

When. Perceptions of appropriate timing to implement shared decision-making models varied between patients and clinicians. In one study, patients stated a preference for the intervention to be provided after diagnosis,⁸⁰ yet another identified a preference for the beginning of the end of life.⁸² From the clinician perspective, one study investigated willingness and perceived capacity to provide basic palliative care, also querying clinician concerns and perceived barriers; the authors concluded that palliative care should be provided to terminally ill patients or during preterminal stages to provide patient and family support.⁹²

For Which Patients. These studies evaluated the implementation of models for integrating palliative care among patients with advanced heart failure,^{80, 91} COPD,⁸¹ and advanced renal disease⁸³ receiving ambulatory care, concluding that palliative care services should be provided for terminally ill and preterminal-stage patients to integrate patient and family support.⁹²

In summary, models to integrate palliative care in ambulatory settings include a variety of components and have been implemented among patients with COPD,⁸¹ end-stage renal disease,⁸³ and advanced heart failure.^{80, 91} These models included communication strategies that facilitate shared decision-making,^{80, 83} defined roles and responsibilities for each team member,⁸⁴ and structured workflows that promote easier integration.⁸⁴ These models were implemented by physicians, advanced practice nurses, social workers, or nurses in ambulatory settings. Although perceptions of the timing of effective implementation of models for integrating palliative care varied among patients and clinicians, no study reported perceptions that palliative care was implemented too early in the course of disease.

Integrative Review

Key Question 1. How can we identify those patients who could benefit from palliative care in ambulatory care settings, and what is the evidence for effectiveness and implementation of these methods?

Although a variety of potential prediction models, tools, and triggers are available as resources, none have been evaluated for effectiveness or implementation for integrating palliative care into ambulatory care. The effectiveness of triggers has been evaluated as part of multimodal interventions. Multimodal intervention studies have combined triggers with clinician training/education for primary care and advanced heart failure. Clinician/stakeholder Key Informants perceived that methods for patient identification and selection such as triggering/reminder systems are helpful, and that time and space to introduce palliative care in the ambulatory care setting is critical. Patient/caregiver Key Informants felt that palliative care options should be provided early and those options should be offered to all patients with serious illnesses.

Key Question 2. What educational resources are available for patients and caregivers in ambulatory care about integrating palliative care, and what is the evidence for their effectiveness and implementation?

Although a variety of relevant patient and caregiver education resources are available, none have been evaluated for effectiveness or implementation for integrating palliative care into ambulatory care. None of the multimodal or implementation studies included patient/caregiver educational resources. Patient/caregiver Key Informants perceived that clinicians should initiate discussions face-to-face and that clarifying the definition of palliative care is key. They also felt that this should be done in a patient-friendly, easily understandable manner and format, aided by educational materials.

Key Question 3. What palliative care shared decision-making tools for serious life-threatening chronic illness or conditions are available for clinicians, patients, and caregivers in ambulatory care, and what is the evidence for their effectiveness and implementation?

Shared decision-making tools relevant to integrating palliative care into ambulatory care all addressed the area of goals-of-care communication or advance care planning only. Palliative care shared decision-making tools may be effective for improving patient satisfaction with communication and advance directive documentation compared with control, but we were unable to draw conclusions about patient depressive symptom scores or caregiver satisfaction. In Table 24, we describe the integration of the implementation evidence with how these factors were included in implementation as part of effectiveness studies, but we were unable to determine evidence for specific factors in effectiveness. Qualitative evidence supported grounding in patient and caregiver experiences of illness, and this was a key component of several shared decision-making tools evaluated for effectiveness. Time constraints, resources, and integration into workflow were raised as concerns in implementation evidence, but all interventions that were evaluated involved additional personnel and resources.

Table 24. Overall integrative synthesis for shared decision-making tools based on adapted Consolidated Framework for Implementation Research¹⁶

Factors for Implementation of Shared Decision-Making Tools	Summary Findings
External factors	<ul style="list-style-type: none"> None of the resources or studies addressed external factors; clinician/stakeholder Key Informants noted performance measures as a potential key factor.
Organizational factors	<ul style="list-style-type: none"> Implementation studies noted concerns about implementation during routine care owing to time constraints; effectiveness studies were not conducted as part of routine care.
Organizational characteristics	<ul style="list-style-type: none"> Effectiveness studies were conducted in both academic and community settings.
Collaboration, resources, and leadership	<p><u>Collaboration</u></p> <ul style="list-style-type: none"> None of the resources, studies, or Key Informants addressed collaboration. <p><u>Resources</u></p> <ul style="list-style-type: none"> All of the interventions evaluated for effectiveness involved additional personnel resources, including providing personalized feedback or trained peer mentors or nurses. <p><u>Leadership</u></p> <p>None of the resources, studies, or Key Informants addressed leadership.</p>
Intervention and implementation characteristics	<p><u>Intervention</u></p> <ul style="list-style-type: none"> Content: Qualitative evidence supported grounding in patient and caregiver experiences of illness, and this was a key component of several shared decision-making tools evaluated for effectiveness. Participants: Qualitative evidence from patients/caregivers supported acknowledging the caregiver's role and empowering and preparing them for open communication with patients. This was a key component of one of the interventions evaluated for effectiveness. Structure: Although qualitative evidence supported that interventions should be time-efficient, specific, and succinct, effectiveness studies also included more lengthy interventions conducted by additional staff outside routine workflow. <p><u>Implementation</u></p> <ul style="list-style-type: none"> Workflow: Although qualitative evidence supported integration into clinical workflow and standardized workflows, this was not generally how effectiveness studies were conducted. Timing: Although qualitative evidence from patients/caregivers supported individualizing timing to preferences, effectiveness studies provided interventions to all eligible patients or based on clinical triggers.
Clinician/team characteristics	<ul style="list-style-type: none"> Qualitative evidence supported that advance care planning should be conducted by the clinician who knows the patient best; effectiveness studies were a mix of supporting primary clinicians and providing supplemental team members.
Patient/caregiver characteristics	<ul style="list-style-type: none"> None of the resources, studies, or Key Informants addressed collaboration.

Key Question 4. What educational resources are available for nonpalliative care clinicians about integrating palliative care in ambulatory settings, and what is the evidence for their effectiveness and implementation?

A variety of clinician education and training resources for nonpalliative care clinicians are available for integrating palliative care into ambulatory care, but only one implementation study and two multimodal studies explicitly evaluated this component. Both clinician/stakeholders and patient/caregiver Key Informants expressed that more education and training is needed for

ambulatory care clinicians. Patient/caregiver Key Informants further perceived that clinician listening skills are especially important.

Key Question 5. What are the models for integrating palliative care into ambulatory settings, and what is the evidence for their effectiveness and implementation?

Models for integrating palliative care were not more effective than usual care for improving HRQOL, had little to no effect on reducing overall symptom burden, and were not effective for improving depressive symptom scores. The models had little to no effect on increasing patient satisfaction but did increase advance directive documentation. Four of the twelve studies about models for integrating palliative care evaluated a shared care model, four used a consultative model, and four used care coordinators or social workers in care. Multimodal interventions incorporating triggers and advance care planning had little to no effect on increasing advance directive documentation. Models for integrating palliative care have included shared care, consultative care, and care coordinator/social worker designs and a wide variety of components, characteristics, and implementation factors, and patients, caregivers, clinicians, and stakeholders perceive them as important (see Table 25); however, we were unable to draw specific conclusions about effects of types of models or specific components, characteristics, and implementation factors or multimodal interventions.

Clinician/stakeholder Key Informants had a number of suggestions for implementation, including integration into and simplification of workflows and documentation, leveraging delivery systems and payment mechanisms, documentation systems, connecting patients to community resources, interdisciplinary care, and integrating quality measurement and improvement. Patient/caregiver Key Informants perceived that clinicians should integrate palliative care into routine care, and that primary care is a key setting (see Table 26).

Table 25. Overall integrative synthesis for components and characteristics of models for integrating palliative care and multimodal interventions

Key Components and Characteristics of Delivery of Integrated Palliative Care	Summary Findings
Introducing palliative care	<ul style="list-style-type: none"> • Included in interventions as shared care consultative care and/or including care coordinators or social workers in care models. • Patient and clinician preferences for timing varied.
Communication	<ul style="list-style-type: none"> • Interventions ideally changed the way systems addressed serious illness communication. <p>Key components include:</p> <ul style="list-style-type: none"> • Addressing relationships • Facilitating better communication about difficult issues • Listening with compassion • Feeling heard
Addressing symptoms	<ul style="list-style-type: none"> • Focus on addressing unmet needs. • Symptom surveys should be focused, as often burdensome and repetitive.
Psychosocial care	<ul style="list-style-type: none"> • Involvement of interdisciplinary team care coordinators, including nurses and social workers, including psychosocial care, was key to many interventions.
Care planning	<ul style="list-style-type: none"> • Often best addressed by clinician who understands the context around their illness and its trajectory. Multimodal interventions used training of the patients' primary or specialty clinicians. • Clinician training is needed, as well as coaching, reminders, and maintenance.

Followup	<ul style="list-style-type: none"> Interventions were generally longitudinal or included reminders. <p>Key components included:</p> <ul style="list-style-type: none"> Linking to community resources Ability to offer individualized solutions

Table 26. Overall integrative synthesis for implementation factors of models for integrating palliative care and multimodal interventions based on adapted Consolidated Framework for Implementation Research¹⁶

Factors for Implementation of Models for Integrating Palliative Care	Summary Findings
External factors	<ul style="list-style-type: none"> Payment mechanisms and performance measures were perceived as important.
Organizational factors	<ul style="list-style-type: none"> Minimizing patient burden was perceived as important to successful implementation.
Organizational characteristics	<ul style="list-style-type: none"> Using existing practice improvement models, strategies, and prioritization was perceived as important to successful implementation.
Collaboration, resources, and leadership	<p><u>Collaboration</u></p> <ul style="list-style-type: none"> Models should build on shared ownership and understanding of specific stakeholder needs. Models benefit from attention to interprofessional relationships. <p><u>Resources</u></p> <ul style="list-style-type: none"> Issues with models include clinician time, costs, and scheduling challenges. We were unable to draw conclusions about effectiveness for costs and resource use for models, and multimodal interventions may have little or no effect. <p><u>Leadership</u></p> <ul style="list-style-type: none"> Involvement can help align palliative care with local programs.
Intervention and implementation characteristics	<p><u>Intervention</u></p> <ul style="list-style-type: none"> Clarifying goals was key, and low-burden interventions were perceived as easier to implement and preferred by patients. A wide variety of characteristics were included in interventions, precluding specific conclusions. <p><u>Implementation</u></p> <ul style="list-style-type: none"> Addressing stakeholder needs and relationships is key. Clarify roles, responsibilities, and costs of interventions.
Clinician/team characteristics	<ul style="list-style-type: none"> Nurses were particularly perceived as useful. Clinician/team involvement in interventions varied and was often not specified, precluding specific conclusions. Interdisciplinary care can be costly and is often not practical outside of funded grants.
Patient/caregiver characteristics	Not addressed

Discussion

Findings in Relation to the Decisional Dilemma

We used a mixed-methods review to address the key decisional dilemma for clinicians, patients, and family caregivers: “How can people with serious life-threatening chronic illness or conditions best receive ambulatory care that better integrates appropriate palliative care approaches?” To address this question, we sought to identify what was available, what was effective, and how to implement the following: resources to identify patients (prediction models, tools, and triggers) and guidelines and position statements, educational materials and resources for patients and caregivers, palliative care shared decision-making tools, palliative care training and educational materials for nonpalliative care clinicians, and models for integrating palliative care and multimodal interventions. We identified 46 Web resources, 20 quantitative effectiveness studies, and 16 qualitative implementation studies relevant to the integration of palliative care into ambulatory care for adults with serious life-threatening chronic illness or conditions other than cancer.

While Key Informants perceived that methods to identify patients are important, no resources on identifying patients for palliative care had evidence about effectiveness or implementation. No relevant patient/caregiver education and training materials had effectiveness or implementation evidence. Patient/caregiver Key Informants emphasized the importance of these materials and perceived that clinicians should initiate discussions face-to-face and that clarifying the definition of palliative care is key. Shared decision-making tools for serious illness or conditions all focused on advance care planning and advance directive (AD) documentation. We found that these tools may be effective for improving patient satisfaction (strength of evidence [SOE]: Low) and increasing AD documentation (SOE: Low); no studies addressed healthcare utilization, costs or resource use. For implementation, studies found that patients and caregivers preferred advance care planning discussions grounded in patient and caregiver experiences of illness, and that timing should be individualized to the specific patient and caregiver. Clinicians preferred tools that were time-efficient, structured, and integrated into workflows.

For nonpalliative care clinician training and educational materials, no studies evaluated effectiveness using objective or patient-centered measures. Both clinician/stakeholder and patient/caregiver Key Informants expressed that more education and training is needed for ambulatory care clinicians; patients/caregivers perceived that listening skills are especially important. The models evaluated for integrating palliative care into ambulatory care were not found to be effective for improving patient health-related quality of life (HRQOL) (SOE: Moderate), may have little to no effect on reducing patient symptom burden (SOE: Low), were not effective for improving depressive symptom scores, but were effective for increasing AD documentation (SOE: Moderate for both) compared with usual care. Patient perceptions of appropriate timing to initiate palliative care varied. No studies reported adverse effects or dropouts related to the interventions. For healthcare utilization, models for integrating palliative were not more effective than usual care for reducing hospitalizations; we were unable to draw conclusions about most other aspects of utilization or cost and resource use. Types of models (shared, consultative, and care coordinator/social worker) and components of interventions varied and interventions were often complex and included a variety of team members, making it difficult to draw conclusions about the effectiveness of specific intervention components.

Several existing systematic reviews of criteria for identification of potential palliative care referrals in outpatient oncology care, across settings and in the electronic medical record, also

found a wide variety of potential tools (including themes such as symptoms, diagnoses, prognosis, and performance status) with little evidence to support standard criteria or impact on patient outcomes.^{4, 95, 96} For patient educational materials, although we did not identify studies on effectiveness, some evidence supports effectiveness of these types of approaches on increasing patient preferences for outpatient palliative care.⁹⁷

Our review of shared decision-making tools focused on those evaluated in patients with serious illness and/or their caregivers. Systematic reviews of shared decision-making tools in broader populations, such as general primary care, have addressed effectiveness of decision aids and tools for advance care planning (ACP).^{98, 99} Tools include ACP forms, patient and clinician educational materials, and Web- and video-based interventions. To date, these interventions have mainly demonstrated effectiveness for improving documentation about ACP and patient-surrogate congruence for preferences; evidence for improving patient/caregiver outcomes is limited. Studies of ADs in broader ambulatory care populations without serious illness have also shown good acceptability for implementation into practice.^{100, 101} A systematic review of palliative care education for primary care physicians, mainly focusing on cancer care, showed some improvement in knowledge but little evidence for patient-centered outcomes.¹⁰²

Other broader reviews of models for integrating palliative care have addressed populations with cancer and non-ambulatory settings, and included non-U.S.-based literature. One Australian-focused rapid review on elements of successful palliative care ambulatory generalist models defined these as “providing a framework or system for the organization of care for people with a progressive life-threatening illness and/or their family, carers or close friends.”⁷ Although our review was unable to identify factors associated with effective implementation in the United States, this review found that integrating palliative care specialist expertise with primary and other ambulatory care services was key to model success. Successful palliative care models addressed complexity of care and increasing patient comorbidity and longevity with serious illness and coordination with complex health systems and their interactions.⁷ Similar to our review, a scoping review focusing on geriatric models across settings found that integrated palliative care focused mainly on symptoms and concerns, with key components of interdisciplinary and person-centered care and education.¹⁰³ As in our review, this review also found that economic analyses were poorly defined.¹⁰³

Other recent systematic reviews of palliative care across settings have found evidence for small effects on the outcome of ACP and not for most other symptoms, as in our review, but did also find small effects on HRQOL and satisfaction.¹⁰⁴ Another review addressing key components associated with effective palliative care across settings found moderate-quality evidence for interdisciplinary care, but only low-quality evidence for early palliative care interventions.¹ A 2019 systematic review of integrated palliative care models in oncology only showed small benefits for short-term (but not long-term) HRQOL, and no effect for symptom burden, depressive symptom scores or healthcare utilization. The review also found insufficient data on intervention elements or integration to draw conclusions; half of the studies included a telephone component.³ A 2016 systematic review of the effect of a wide variety of palliative care interventions on economic outcomes found no evidence for beneficial effects.¹⁰⁵

Strengths and Limitations

The evidence for better integration of palliative care into ambulatory care for adults with serious life-threatening chronic illness or conditions included studies of a wide variety of interventions, illnesses and settings, and outcomes. Although many proposed prediction models, tools, and triggers exist, studies of triggers generally only address their accuracy for prediction, rather than their implementation or their effect on patient or caregiver outcomes. One implementation study and two effectiveness studies did include triggers as a key part of the multimodal intervention. Patients with certain characteristics can ‘trigger’ a prompt or action, which then may lead to an intervention, which may or may not be accepted, which may lead to an improved outcome. Failure can occur at any step along this causal pathway. The number of studies on shared decision-making tools was relatively small, as most existing literature does not address serious illness populations or evaluate patient and caregiver outcomes. All shared decision-making tools addressed goals-of-care communication and ACP and no other palliative care domains, such as symptom management.

We identified only one study of clinician education assessing implementation; published effectiveness studies of clinician education did not include objective measures, such as knowledge or patient-centered outcomes, but only subjective clinician outcomes, such as self-reported confidence or satisfaction. The lack of strong evidence assessing models for integrating palliative care reflects the literature, which often lacks controlled designs and evaluates only model processes and not patient or caregiver outcomes. We did not identify any mixed-methods or process evaluation studies or studies comparing implementation using different strategies or settings.

Studies included in our review had a variety of limitations, including lack of standard information on details of the interventions and how and how well they were implemented or addressed contextual issues, making comparisons across studies challenging. Outcomes were measured using a variety of assessment tools, many of which are not validated for palliative care populations. Owing to missing information and variation in outcomes measured, we were able to conduct only a few meta-analyses. Furthermore, most of the quantitative studies were at high risk of bias and qualitative studies often lacked rigorous reporting or methods. Adverse effects and burden and costs to patients and caregivers were not reported in any studies. Dropouts were generally not characterized as to whether they were related to the intervention or its burdens. Outcomes of shared decision-making tools were often short-term. Long-term sustainability/implementation issues were not evaluated, which is particularly important as all interventions were supported by external funding and required significant additional resources. Although most common serious chronic conditions, such as advanced heart failure, chronic obstructive pulmonary disease (COPD), and end-stage renal disease (ESRD) were represented in at least some Web resources and studies, few Web resources and none of the studies addressed the important ambulatory palliative care issues of multimorbidity or frailty. We identified little relevant information on education, for patients and caregivers or for clinicians.

Our review also had several limitations. Our Web resources search was limited to information posted on websites and resources clearly focused on integrating palliative care into ambulatory care. The search was also limited to key U.S. national palliative care, health professional, and consumer organizations information posted on the Web; and it did not include the wide variety of resources available through many health systems, individual states, and other private organizations. Although we focused on shared decision-making tools evaluated in serious chronic illness populations, tools evaluated for broader populations may be appropriate and

relevant and, thus, much of this evidence may also be applicable. Since models for other countries' health systems are often not translatable to the U.S. context, we did not include these in our review, although some findings may be applicable to the U.S. context. We used accepted standards for clinically meaningful differences, but these were not all from palliative care populations and some might consider these smaller differences meaningful.

Applicability

The evidence did not support specific conclusions for patients with specific illnesses; the studies of both shared decision-making tools and models most commonly included ESRD, COPD, and heart failure populations. However, the conclusions may be applicable to other patients with serious illness. Studies of shared decision-making tools addressed only goals-of-care communication and ACP and did not address other domains of palliative care, including symptom management. These studies also focused on in-person, often resource-intensive interventions. Trials of different methods of incorporating shared decision-making tools into ambulatory care for serious illness, such as patient-self management and Web and electronic health record portal interventions, are ongoing.^{106, 107}

Models used shared care, consultative care, or the incorporation of care coordinators or social workers into care as methods of integration. Many interventions were evaluated only in academic settings, and results may not be translatable to community settings. All studies had external funding; it may not be financially practical to translate results into actual clinical practice using the same intensity of intervention. Finally, none of the studies of models or multimodal interventions, and few of the studies about shared decision-making tools, included the caregiver perspective or outcomes, which is critical in the provision of palliative care for patients with serious illness.

Implications for Clinical Practice, Education, Research, or Health Policy

In terms of clinical practice and health policy, this systematic review found evidence of acceptability to patients, caregivers, and clinicians for both shared decision-making tools and models to integrate palliative care approaches. These have been successfully implemented into a variety of ambulatory care settings and have some evidence for effectiveness in a variety of settings and populations. Shared decision-making tool interventions addressed both goals-of-care communication and ACP and included approaches to facilitate interventions by patients' usual clinicians and those involving interventionists or peers; interventions generally focused on patients' broader preferences, goals and values, and communication, rather than specific end-of-life decisions. Models that focused on approaches of shared care and the incorporation of care coordinators or social workers into practice and interdisciplinary care, particularly with nurses, was a key factor.

In terms of future research, for shared decision-making tools, more research is needed beyond one-time ACP and outcomes beyond ADs completion, and for broader serious illness communication and symptom management. For models for integrating palliative care, more research is needed on combined approaches with different options for patients, where different options and their timing can be tailored to patient and caregiver circumstances and preferences. These patients have many symptoms, needs, and concerns and often have multiple chronic illnesses that affect their care and HRQOL; studies should address palliative care that addresses

these complex issues, and overall symptom burden should be included as an important outcome. Interventions were often complex and multifaceted but did not evaluate the potential impact of specific components; research addressing this issue might help lead to interventions that are targeted and potentially less burdensome, less costly, and easier to implement in real-life, busy ambulatory practice workflow. Most studies had major methodologic limitations; the quality of the evidence and ability to synthesize study results would be improved by following established criteria for high-quality palliative care clinical trials, including clear descriptions of intervention components and the fidelity and quality of delivery, recruitment and retention, and choice of outcomes validated for palliative care, outcome measurement, and analysis.¹⁰⁸⁻¹¹⁰

A major challenge of the palliative care interventions literature continues to be the wide variety of outcomes measured in studies and frequent use of a variety of measurement instruments or reporting, making synthesis and conclusions difficult. Similarly, qualitative implementation studies should follow established criteria for quality qualitative research.^{14, 111} Measuring cost and resource use, both of the intervention itself and as an outcome, is critical and future studies should follow established best practices for economic evaluations, generally, and palliative care, specifically.^{111, 112} The cost and burden to patients and caregivers and other adverse effects, such as medication side effects, are critical issues for patients but were not included in any of these studies and should be addressed in future studies, as well. Studies of specific serious illnesses may not be relevant to populations with frailty or multimorbidity, and these groups should be included or focused on in future research, particular given the growing needs of the aging U.S. population. None of these studies specifically addressed health equity or disparities as part of the intervention, which are critical to patient-provider care in ambulatory settings and future cultural appropriate intervention research.

In terms of answering the decisional dilemma and implications for the Agency for Healthcare Research and Quality Learning Health Systems Panel, these interventions mainly add additional staff or processes to existing systems of care with little to no impact on outcomes. These patients often have intense, varying and complex care needs and are treated across settings and in the community. Developing and implementing rigorous studies or systems of care that work for this population is challenging. As noted in the recent National Academies of Medicine Report, *Dying in America*, and subsequent discussion papers and workshops, improving care for those with serious, life-threatening illness and conditions requires comprehensive, individualized, often time-consuming care and systems oriented towards their needs and coordination with community services.^{113, 114} For clinician-patient communication about palliative care, given that frequent and often detailed conversations about the end of life are needed, the *Dying in America* report recommends better systems support and infrastructure for improved communication skills and the time for these conversations, which generally require involvement from nonpalliative care clinicians. For policy, the report recommends that the healthcare system and payment structures need to also support other important domains in palliative care, including symptom management and care coordination, and improve home support and social services and their integration with medical care. The interventions we identified address aspects more relevant to clinicians, such as advance directives and prescribing medications for symptoms, rather than those that may matter more to patients and caregivers, such as function, coordination of care, and caregiving needs.¹¹⁴ In addition, other research has found that little evidence exists on effective interventions for common symptoms in palliative care, and ongoing research and drug development are sparse; advances in the science of symptom management in these populations are needed for interventions evaluating models to impact these outcomes.¹¹⁵

For U.S. health policy, as U.S. healthcare is currently moving to less visit-based models, with changes from the proposed Centers for Medicare and Medicaid Innovation Primary Care First and Serious Illness Population models and changes in care accelerated by the COVID-19 pandemic, models for integrating palliative care may become of increased importance and ongoing evaluations of telehealth for care delivery will be particularly valuable. These results on the effectiveness of successful integration could also have implications for earlier provision of palliative care services for patients with serious illness, including initiatives by the Centers for Medicare and Medicaid Innovation and private insurers, which could be more effective and efficient with better integration into ongoing ambulatory care for these patients. Other methods for improving the efficiency of palliative care integration could include linking palliative care triggers to approaches in growing use by payors and systems to identify patients with or at high risk for healthcare utilization for care management.

Conclusions

For better integration of palliative care into ambulatory care for serious life-threatening chronic illness or conditions other than cancer, ACP shared decision-making tools may increase patient satisfaction and AD documentation. The models evaluated for integrating palliative care were not effective for improving HRQOL and had little to no effect on reducing overall symptom burden and were not effective for improving depressive symptom scores, but were effective for increasing AD documentation. Further research is particularly needed on identification of patients; educational materials for patients, caregivers, and clinicians; shared decision-making tools beyond ACP and AD completion; specific components, characteristics, and implementation factors in models to integrate palliative care into ambulatory care; and when and how to integrate palliative care among those with frailty and/or multimorbidity. Further research also needs to consider the real-life and most important concerns of those impacted by serious illness and conditions. Fundamental changes in the healthcare system and advances in the science of palliative care are needed to improve palliative care approaches in ambulatory care to better improve patient- and caregiver-centered outcomes.

Abbreviations

AAICP = Advanced illness coordinated care program
ACP = Advance care planning
AD = Advance directive
AHRQ = Agency for Healthcare Research and Quality
ANOVA = Analysis of variance
APNs = Advanced Practice Nurses
CASA = Collaborative care to alleviate symptoms and adjust to illness
CHF = Congestive heart failure
CI = Confidence interval
CCT = Comprehensive care team
CINAHL=Cumulative Index of Nursing and Allied Health Literature
COPD = Chronic obstructive pulmonary disease
COVID-19 = Coronavirus disease 2019
CT = Controlled trial
DPOA-HC = Durable Power of Attorney for Health Care
ED = Emergency department
ESAS = Edmonton Symptom Assessment Scale
EPC = Evidence-based Practice Center
ESRD = End stage renal disease
FACIT-PAL = Functional Assessment of Chronic Illness Therapy – Palliative Care scale
GAD-7 = Generalized Anxiety Disorder scale 7-item
GOLD = Global Initiative for Chronic Obstructive Lung Disease
HADS = Hospital Anxiety and Depression Scale
HRQOL = Health-related quality of life
ICD-10 = International Classification of Diseases, tenth revision
ICU = Intensive care unit
IQR = Interquartile range
KCCQ = Kansas City Cardiomyopathy Questionnaire
KIs = Key Informants
KQ = Key Question
LACE = Length of stay, acuity of admission, comorbidities, emergency department visits
LVAD = Left Ventricular Assist Devices
NA = Not available
NR = Not reported
NYHA = New York Heart Association
PCDM = Patient-centered disease management
PCMH = Patient-centered medical home
PEG = Pain intensity, enjoyment of life, general activity
PHQ-9 = Patient Health Questionnaire 9-item
PHQ-8 = Patient Health Questionnaire 8-item
POLST = Provider Orders for Life-Sustaining Treatment
PRISMA = Preferred Items for Reporting in Systematic Reviews and Meta-Analyses
RCT = Randomized clinical trial
ROBINS-I tool = Risk of Bias Assessment Tool for Non-Randomized Studies of Interventions
RR = Relative risk

SD = Standard deviation

SDM-RSC = Shared Decision-Making and Renal Supportive Care

SE = Standard error

SMD = Standardized mean difference

SOE = Strength of evidence

SPICT = Supportive and palliative care indicators tool

SPIRIT = Sharing Patients' Illness Representation to Increase Trust

TEP = Technical Expert Panel

VA = Veterans Affairs

Appendix A. Methods

Details of Study Selection

Search Strategy

Part (a)

We searched key websites from health care professional organizations relevant to primary care, including specialties and palliative care, and other established relevant Federal government and national U.S. nonprofit and patient organization Web resources in March 2020 (Table A-1). We limited the search to resources that had been developed or updated within the last 5 years given significant changes in evidence and guidelines in ambulatory palliative care.

Part (b)

We searched the following databases for quantitative studies: PubMed, CINAHL, and the Cochrane Central Register of Controlled Trials January 2000 to May 20, 2020 (the year 2000 is the start of the palliative care movement in the U.S. and ambulatory palliative care programs were not available before that year). We developed a search strategy for PubMed, based on an analysis of the medical subject headings (MeSH) terms and text words of key articles identified a priori.

We hand searched the reference lists of included articles and relevant systematic reviews. We looked for relevant studies during our search of websites (part a).

Part (c)

As part of the searches for part (b), we also searched for qualitative, mixed methods and process evaluation studies. We also modified the search strategy from Part (b) to search for systematic reviews of qualitative studies.

We used DistillerSR (Evidence Partners, 2020), a Web-based database management program, to manage the screening process for studies.¹ All citations identified by the search strategies were uploaded to the system and reviewed in the following manner:

Abstract screening: Two reviewers independently reviewed abstracts. Abstracts were excluded if both reviewers agreed that the article met one or more of the exclusion criteria (Table A-8). Differences between reviewers regarding abstract eligibility were tracked and resolved through consensus adjudication. Relevant reviews, including systematic reviews and meta-analyses, were tagged for a references list search.

Full-text screening: Citations promoted based on abstract review underwent another independent parallel review using the full-text of the articles. Any differences regarding article inclusion were tracked and resolved through consensus adjudication.

Inclusion and Exclusion Criteria

Part (a)

Criteria for inclusion and exclusion of Web resources are based on the Key Questions and are briefly described in Tables A-9 and A-10 (eligible Web resources had to meet all criteria, be from one of the key national US websites as in the search strategy and Table A-1, and have specific relevance to the integration of palliative care into ambulatory care for non-cancer serious chronic illness or conditions). We reviewed U.S. key national websites to which we had either free access or memberships, and based inclusion on available descriptions of materials on the websites.

Table A-8. Specific inclusion criteria for web resources

Type	Criteria
Content	Relevant to any of the interventions
Language/Country	English/United States
Admissible evidence	Web resource developed or updated in past 5 years.

Part (b)

The eligible studies had to meet all of the following criteria: (1) included adults 18 years of age and older with serious life threatening chronic illness or conditions (other than those only with cancer) and their caregivers, being seen in ambulatory settings; (2) included prediction models, tools, or triggers to identify patients for palliative care in ambulatory settings (KQ1); (3) included educational materials and resources for patients and/or caregivers about palliative care in ambulatory settings (KQ2); (4) included palliative care shared decision-making tools and resources for clinicians and patients and/or caregivers in ambulatory settings (KQ3); (5) included palliative care training or educational materials for ambulatory settings (KQ4); (6) included models for integrating palliative care or multimodal interventions in ambulatory settings (KQ5); (7) reported outcomes of interest; (8) randomized controlled trial or non-randomized trial with a concurrent or historical comparison group (controlled trial or prospective cohort study) (all KQ part b, effectiveness questions); (9) published in English; and, (10) U.S.-based.

The criterion for outcomes was applied at the full-text screening level only. An overview of the PICOTS inclusion and exclusion criteria is provided in Table 3.

Part (c)

The criteria for inclusion and exclusion of qualitative, mixed-methods and process evaluation studies were based on the Key Questions and are described in Table A-10.

Table A-9. PICOTS: Inclusion and exclusion criteria for quantitative studies

Type	Inclusion	Exclusion
Population	Patients (≥ 18 years of age) with serious life-threatening chronic illness or conditions (other than those only with cancer) and their caregivers, being seen in ambulatory settings (KQs 1,2,3,5) Clinicians practicing in ambulatory settings (KQ4)	Studies with only cancer patients Studies not focusing on ambulatory populations Studies of clinicians caring only for cancer patients Studies focusing on trainees
Interventions	KQ1: prediction models, tools, or triggers to identify patients for palliative care in ambulatory settings KQ2: educational materials and resources about palliative care for patients and/or caregivers in ambulatory settings KQ3: palliative care shared decision-making tools and resources for clinicians and patients and/or caregivers in ambulatory settings KQ4: palliative care training or educational materials for ambulatory settings KQ5: models for integrating palliative care or multimodal interventions in ambulatory settings	Studies that report no intervention of interest
Comparisons	KQ1: prediction models, tools, or triggers to identify patients for palliative care in ambulatory settings KQ2: educational materials and resources about palliative care for patients and/or caregivers in ambulatory settings KQ3: palliative care shared decision-making tools and resources for clinicians and patients and/or caregivers in ambulatory settings KQ4: palliative care training or educational materials for ambulatory settings KQ5: models for integrating palliative care or multimodal interventions in ambulatory settings Usual care for all KQs	Studies that do not report the comparisons of interest

Type	Inclusion	Exclusion
Outcomes	<p>Intermediate Knowledge (clinicians, patients, caregivers) (KQ2, KQ4)</p> <p>Awareness (clinicians, patients, caregivers) (KQ2, KQ4)</p> <p>Skills (clinicians) (KQ4)</p> <p>Final (All apply to all KQ) (In hierarchy from patient-centered to clinician to health system. All patient or caregiver-reported outcomes must be measured by a validated instrument.²)</p> <p>Patient or caregiver satisfaction</p> <p>Patient or caregiver health-related quality of life</p> <p>Patient or caregiver symptoms of depression, anxiety, or psychological well-being</p> <p>Caregiver burden, caregiver impact, or caregiver strain</p> <p>Patient symptoms or symptom burden (includes multidimensional symptom tools and key symptoms of pain, dyspnea, fatigue); this must include patient-reported symptom measurement (or caregiver-reported for patients unable to report)</p> <p>Concordance between patient preferences for care and care received</p> <p>Clinician job satisfaction or burnout, perceptions of teamwork</p> <p>Healthcare utilization (use and length of hospice care, hospitalizations, advance directive documentation) and costs and resource use (use of outpatient clinician services, including palliative care)</p> <p>Adverse effects</p> <p>Medication side effects</p> <p>Dropouts</p>	<p>Studies that do not report the outcomes of interest</p> <p>Excludes clinician self-report for intermediate outcomes</p>
Type of Study	<p>Randomized controlled trials</p> <p>Non-randomized studies with concurrent or historical controls</p>	<p>Articles published prior to the year 2000</p> <p>Non-English publications</p> <p>Case reports or case series</p> <p>Publications with no original data (e.g., editorials, letters, comments, reviews)</p> <p>Full text not presented or unavailable, abstracts only</p>
Timing and Setting	<p>Any timing</p> <p>Ambulatory care settings</p> <p>U.S.-based studies</p>	<p>Hospital setting</p> <p>Oncology setting</p> <p>Emergency department</p> <p>Nursing home and long-term care facilities</p>

Table A-10. Specific inclusion and exclusion criteria for qualitative, mixed-methods and process evaluation studies

Criteria	Inclusion	Exclusion
Comparison	No comparison group needed	
Type of study	Systematic reviews of qualitative studies Qualitative or mixed-methods studies: include studies that use a formal qualitative data collection method (e.g., interviews, focus groups, or ethnography) and analysis methods (e.g., phenomenological, grounded theory, ethnographic and thematic analysis studies) Process evaluation studies (type of implementation studies) including studies that address in results: Identifying/addressing barriers/facilitators Populations to target Mechanisms for success/failure	Qualitative studies: observation or artifact analysis Process evaluation studies focusing only on research issues (e.g., fidelity, participant recruitment, intervention quality, participant engagement)
Sample size		Analysis of interest includes fewer than 10 participants

Table A-11. Minimal clinically important differences and clinical cutoff scores for outcome assessment tools included in review

Domain/ Instrument	Scale	Minimal Clinically Important Differences (MCIDs)	Clinical Cutoff Scores
Patient Satisfaction			
Group Health Association of America Consumer Satisfaction Survey	20 - 100	None identified	None identified
Investigator constructed 5-point, Likert type scale	0 - 5	None identified	None identified

Montgomery Borgatta Caregiving Burden – Stress Burden subscale ³⁰	4 - 20	None identified	>13.5 (high score)

Data Extraction

We created and pilot tested standardized forms for data extraction. Each Web resource or article underwent double review by the study investigators for data abstraction. The second reviewer confirmed the first reviewer's abstracted data for completeness and accuracy. A third reviewer audited a sample of articles by the first two reviewers to ensure consistency in the data abstraction of the articles.

For all articles, reviewers extracted information on general study characteristics (e.g., study design, study period, and follow-up), study participant characteristics, eligibility criteria, interventions, outcome measures and the method of ascertainment, and the results of each outcome, including measures of variability. We completed the data abstraction process using forms created in Excel (Microsoft, Redmond, WA). We used the Excel files to maintain the data and to create detailed evidence tables and summary tables.

Risk of Bias Assessment of Individual Quantitative Studies

Two reviewers independently assessed risk of bias for each quantitative study. For RCTs, we used the Cochrane Risk of Bias Tool, Version 2.³¹ For non-randomized studies, we used the Cochrane Risk of Bias Assessment Tool for Non-Randomized Studies of Interventions (ROBINS-I tool).³² Differences between reviewers were resolved through consensus.

We assessed the individual risk of bias for RCTs using five items:

Risk of bias arising from the randomization process;

Risk of bias due to deviations from the intended interventions: effect of assignment to intervention, and effect of adhering to intervention;

Risk of bias due to missing outcome data;

Risk of bias in measurement of the outcome;

Risk of bias in selection of the reported result.

Following the ROB2 guidance, concerns were expressed only about issues that are likely to affect the ability to draw reliable conclusions from the study. In reaching final judgements, the following considerations applied: judgement of 'High' risk of bias for any individual domain will lead to the result being at 'High' risk of bias overall, and a judgement of 'Some concerns' for any individual domain will lead to the result being at 'Some concerns', etc.

We assessed the individual risk of bias for non-randomized and cohort studies using 7 items:

Bias due to confounding;

Bias in selection of participants into the study;

Bias in classification of interventions;

Bias owing to deviations from intended interventions;

Bias owing to missing data;

Bias in measurement of outcomes;

Bias in selection of the reported results.

Following the ROBINS guidance, judgements were made using the following algorithm:³²

low risk of bias: the study is judged to be at low risk of bias for all domains,

moderate risk of bias: the study is judged to be at low or moderate risk of bias for all domains,

serious risk of bias: the study is judged to be at serious risk of bias in at least one domain, but not at critical risk of bias in any domain,

critical risk of bias: the study is judged to be at critical risk of bias in at least one domain,

no information: there is no clear indication that the study is at serious or critical risk of bias and there is a lack of information in one or more key domains of bias (a judgement is required for this).

Assessment of Quality of Qualitative Studies

For qualitative studies, we conducted quality assessment, as risk of bias is not relevant. We used the Joanna Briggs Institute Quality Appraisal Checklist^{33, 34} to address elements specific to our key questions. Two reviewers independently assessed the methodological quality and resolved differences through consensus.

Data Synthesis and Analysis

For part (b) of each Key Question, we created a set of detailed evidence tables containing all information extracted from eligible studies (see Appendix D). These tables include details of what is included in the interventions; for example, for models of care, details extracted include what disciplines are involved, mode of contact, and content of the intervention. Tables also include details of implementation of the interventions as described in these studies, such as clinician training provided. We synthesized all studies qualitatively. We conducted meta-analyses for outcomes with at least three studies and the studies were sufficiently homogeneous with respect to key variables (population characteristics, study duration, and intervention). Randomized controlled trials and nonrandomized studies were analyzed separately. Statistical significance was set at a two-sided alpha of 0.05. Statistical heterogeneity among studies was evaluated using an I^2 statistic and anticipated statistical heterogeneity. For continuous outcomes, a standardized mean difference was calculated using a random-effects model with DerSimonian and Laird formula. All meta-analyses was conducted using STATA version 14 (College Station, TX).

For part (c) of each key question, we summarized the results of the qualitative studies into categories for each KQ, informed by discussions with our Key Informants. We conducted a review of the qualitative studies to address mechanisms and context for part (c) of each KQ where studies were identified. We based our methods on the 2017 Cochrane guidance, *Qualitative and Implementation Methods Group Guidance Paper 5: Methods for integrating*

*qualitative and implementation evidence within intervention effectiveness reviews*³⁵ and Joanna Briggs Institute methods for mixed methods systematic reviews.³⁶

For parts (b) and (c) of each key question, model definitions were derived from previous work and revised based on consensus.³⁷ Once established, two researchers independently reviewed each citation to determine model type.

Finally, we completed an integrative review. The Cochrane guidance defines the integrative review as “combining the findings from different types of studies to produce a more comprehensive synthesis of the evidence on ‘what works’”, recognizing that a variety of contextual factors, such as characteristics of the local population or setting, are key to intervention implementation and effectiveness (under “real world” conditions). Through the incorporation of qualitative and mixed methods research, the integrative review process can incorporate the patient and caregiver perspective, which is critical for palliative care, and the practicing clinician and health system perspective, which is critical for the integration of palliative care in the ambulatory setting. We completed integration by juxtaposing the findings from the grey literature (part (a) in each question) with the systematic review (part (b) in each question) with the identified categories from the review of qualitative studies (part (c) of each question). We focused particularly on KQ3 and KQ5 where studies were identified across all parts. We integrated categories of what is available (e.g., components of what is included in integrated palliative care interventions) from qualitative studies with evidence from effectiveness studies. We used categories informed by models of what is included in integrated ambulatory palliative care³⁸, the Consolidated Framework for Implementation Research (CFIR) adapted for complex interventions³⁸, a prior AHRQ project on key implementation factors for quality and safety studies³⁹, and refined through Key Informant input. This process helped address, in particular, the elements of the part (c) questions on why and how some types of interventions may be effective and others are not, when and which patients may benefit from these interventions, and how palliative care approaches can best be integrated into ambulatory care.

Grading the Strength of the Body of Evidence

At the completion of our systematic review, we graded the strength of evidence on critical outcomes for quantitative studies by using the grading scheme recommended by the Methods Guide for Conducting Comparative Effectiveness Reviews. We defined the critical outcomes as those most important for making decisions; we identified these a priori with input from the Technical Expert Panel.

The critical outcomes include:
Patient health-related quality of life
Patient symptom burden
Patient symptoms of depression
Patient satisfaction
Caregiver satisfaction
Advance directive documentation

Following this standard EPC approach, for each critical outcome, we assessed the number of studies, their study designs, the study limitations (i.e., risk of bias and overall methodological quality), the directness of the evidence to the Key Questions, the consistency of study results, the precision of any estimates of effect, the likelihood of reporting bias, and the overall findings across studies. Based on these assessments, we assigned a strength of evidence rating as being either high, moderate, or low, or insufficient evidence to estimate an effect or draw a conclusion (Table 5). Investigators writing each section completed the strength of evidence grading. The team members reviewed the assigned grade and conflicts were resolved through consensus. We used the grading scheme recommended in the AHRQ Methods Guide for Effectiveness and Comparative Effectiveness Reviews (Methods Guide). We considered the following domains: study limitations, directness, consistency, and precision.⁴⁰

We classified the strength of evidence pertaining to the KQs into four categories:

High (high confidence that the evidence reflects the true effect and further research is very unlikely to change our confidence in the estimate of effect)

One or more RCTs

Low study limitations

Direct, consistent, and precise

Moderate (moderate confidence that the evidence reflects the true effect, and further research may change our confidence in the estimate of effect)

One or more RCTs

Low study limitations, and some concerns

Direct, consistent, and precise

Low (low confidence that the evidence reflects the true effect and further research is likely to change our confidence in the estimate of the effect and is likely to change the effect estimate)

One or no RCT

High study limitations or some concerns

At least two of the following: indirect, inconsistent, or imprecise

Insufficient (evidence is unavailable or insufficient to assess with any confidence).

One or no RCT

High study limitations for RCTs or serious or critical study limitations for a cohort study

At least two of the following: indirect, inconsistent, or imprecise

Table A-12. Definitions of the grades of overall strength of evidence

Grade	Definition
High	We are very confident that the estimate of effect lies close to the true effect for this outcome. The body of evidence has few or no deficiencies. We believe that the findings are stable (i.e., another study would not change the conclusions).
Moderate	We are moderately confident that the estimate of effect lies close to the true effect for this outcome. The body of evidence has some deficiencies. We believe that the findings are likely to be stable, but some doubt remains.
Low	We have limited confidence that the estimate of effect lies close to the true effect for this outcome. The body of evidence has major or numerous deficiencies (or both). We believe that additional evidence is needed before concluding either that the findings are stable or that the estimate of effect is close to the true effect.
Insufficient	We have no evidence, we are unable to estimate an effect, or we have no confidence in the estimate of effect for this outcome. No evidence is available, or the body of evidence has unacceptable deficiencies, precluding reaching a conclusion.

Peer Review and Public Commentary

We invited experts in palliative care and individuals representing stakeholder and user communities to provide external peer review of this review; AHRQ and an associate editor also provided comments. We posed the revised draft report on the AHRQ website for four weeks to elicit public comment (posted 5 August 2020). Reviewer comments were addressed, revising the report as appropriate. A disposition of comments table of peer and public comments was posted on the EHC website three months after the Agency posted the final review.

Definition of Terms

The following definitions are used in this report.

Ambulatory settings: Includes settings such as hospital outpatient departments and clinicians' offices, particularly primary care, but also including geriatrics, nephrology, pulmonology, cardiology and neurology

Chronic illness: An illness that lasts one year or more and requires ongoing medical attention and/or limits activities of daily living.

Clinician: A healthcare professional qualified in the clinical practice of medicine, such as physicians, nurses, pharmacists, social workers, or other allied health professionals.⁴¹

Consultative care model: An approach to care delivery where a clinician serves in a consultant role with provision of palliative advice and does not necessarily assume primary responsibility of care.⁴²

Educational materials and resources: Include pamphlets, curricula, Web sources, and videos designed to provide information about integrating palliative care and palliative care options in ambulatory care.

Guidelines and position statements: Clinical practice guidelines and position statements from key U.S. health care professional and other organizations specifically relevant to integrating palliative care into serious illness chronic care.

Integrative review: This method allows for the combination of diverse methodologies.⁴³ We use this approach to examine qualitative and process evaluation literature (such as interviews with patients and families and implementation studies) to address how interventions work and evidence for how they should best be included in care, and to integrate this with the effectiveness literature. Combining the findings from different types of studies to produce a more comprehensive synthesis of the evidence on 'what works' and how.³⁵

Multimodal interventions: For the purposes of this review, combinations of the different types of included specific interventions: identification of patients, education for patients and caregivers, shared decision-making tools, and/or clinician education.

Models: Care delivery structures.

Palliative care: Care, services, or programs for patients with serious life-threatening illness and conditions and their caregivers, with the primary intent of relieving suffering and improving health-related quality of life, including dimensions of physical, psychological/emotional, social, and spiritual well-being.³⁶ Note that other terms, such as supportive care, may be similarly used. Hospice care is a type of palliative care but is not included in this review as it is not delivered in ambulatory care.

Patient education: This can be conducted either individually or as part of a group or community, including through methods such as in-person, telephone, online or other electronic, print or audio-visual educational materials.³⁷

Prediction models: Modeling of patient and illness factors to predict the likelihood of patient outcomes, such as hospitalizations.

Primary palliative care: Care in palliative care domains for relevant populations provided by non-palliative care specialists, such as by primary care clinicians.⁴⁴

Process evaluation (also a type of implementation study): Research focusing on mechanisms (how and why something can be successfully implemented) and contextual issues (population, setting, barriers and facilitators).³⁵ Process evaluation studies include process studies that report on why and how interventions work with similar interventions, health conditions and contexts.⁴⁵ They may be:

conducted alongside effectiveness studies

conducted after the effectiveness study on the same groups

unrelated to effectiveness studies

Provider education: Used to describe a variety of interventions including educational workshops, meetings (e.g., traditional Continuing Medical Education [CME]), lectures (in-person or computer-based), educational outreach visits (by a trained representative who meets with providers in their practice settings to disseminate information with the intent of changing the providers' practice). The same term also is used to describe the distribution of educational materials (electronically published or printed clinical practice guidelines and audio-visual materials).⁴⁶ This review focuses on materials that include education about integrating palliative care into ambulatory care.

Shared care model: An approach to care delivery where there is joint participation of non-palliative clinicians and palliative care clinicians working together in relation to an individual's care. Shared care models may also include systematic cooperation where different systems work together with various levels and disciplines of clinicians.⁴⁷

Shared decision-making tools: These are patient-facing and/or clinician-facing tools to help make decisions that reflect medical evidence and patient goals for care relevant to palliative care, such as advance care planning tools to aid with decisions about treatment options and preferences for future care.⁴⁸ For the purposes of this review, we focused on tools for serious illnesses and conditions in ambulatory care.

Triggers: Also known as screening criteria; indicators that someone may benefit from palliative care services. These may include patient or disease characteristics, palliative care needs, functional status decline or persistent or worsening symptoms, or high health care needs.

Website: A collection of Web pages which are grouped together and connected.

Webpage: Document which can be displayed in a Web browser.

Web resource: Specific resource listed on a Web page.

Appendix C. Results

Search Results Part (a)

We reviewed 139 Web pages (Figure C-1) and included 46. Appendix B lists the excluded Web pages.

Figure C-1. Summary of the website search Part (a)

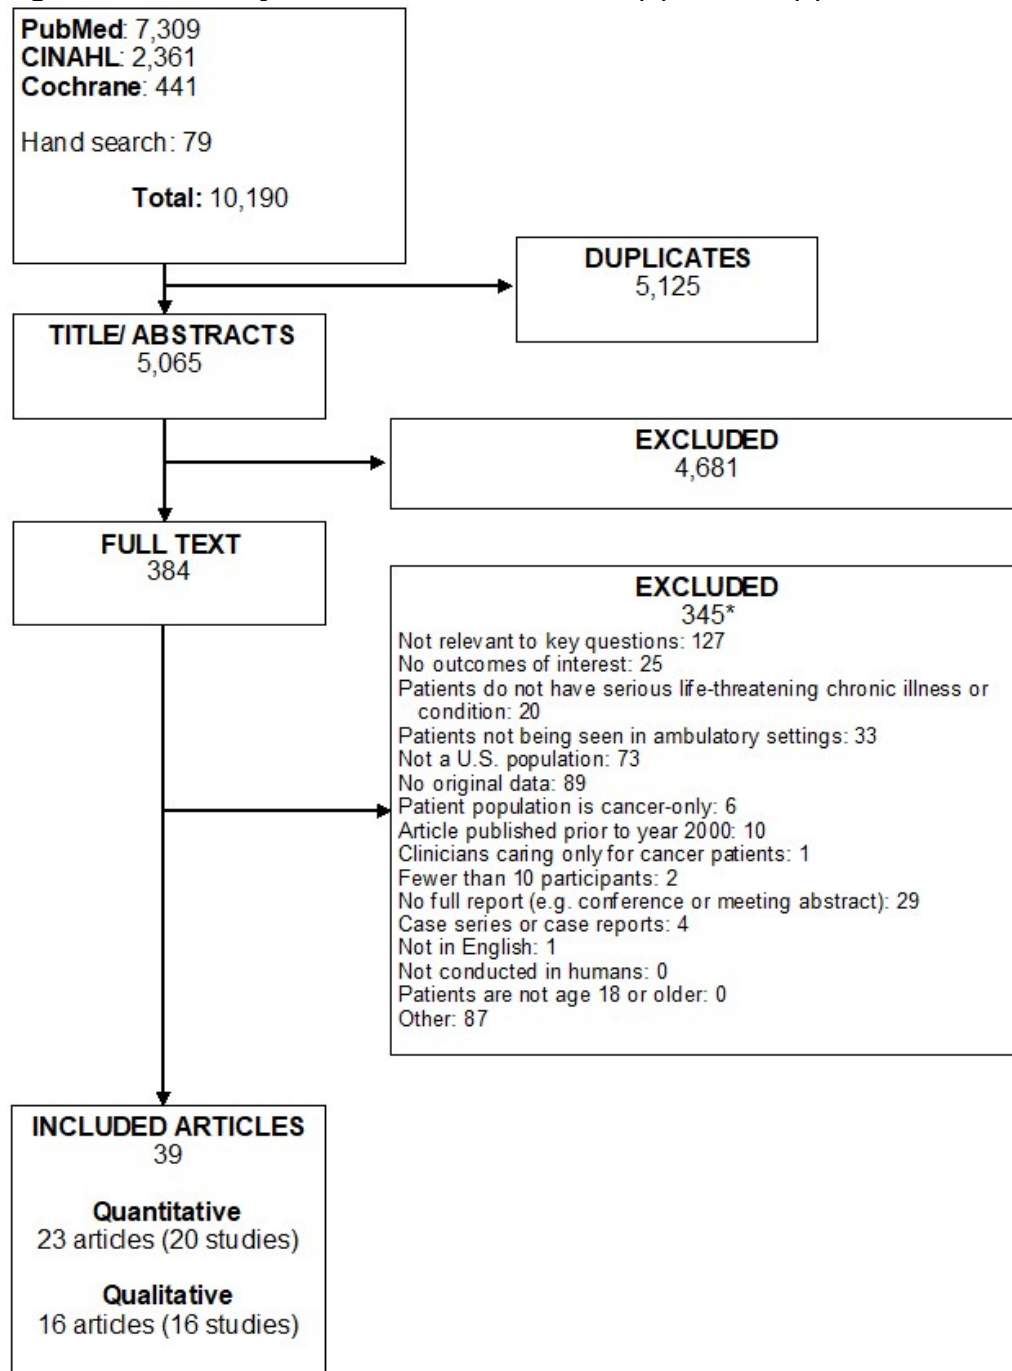

EPEC=Education in Palliative & End-of-life Care

Search Results Part (b) and Part (c)

We retrieved 5,065 unique citations (Figure C-2). After screening abstracts and full-text, we included 39 articles reporting 36 studies. Appendix B lists the excluded articles.

Figure C-2. Summary of the literature search Part (b) and Part (c)

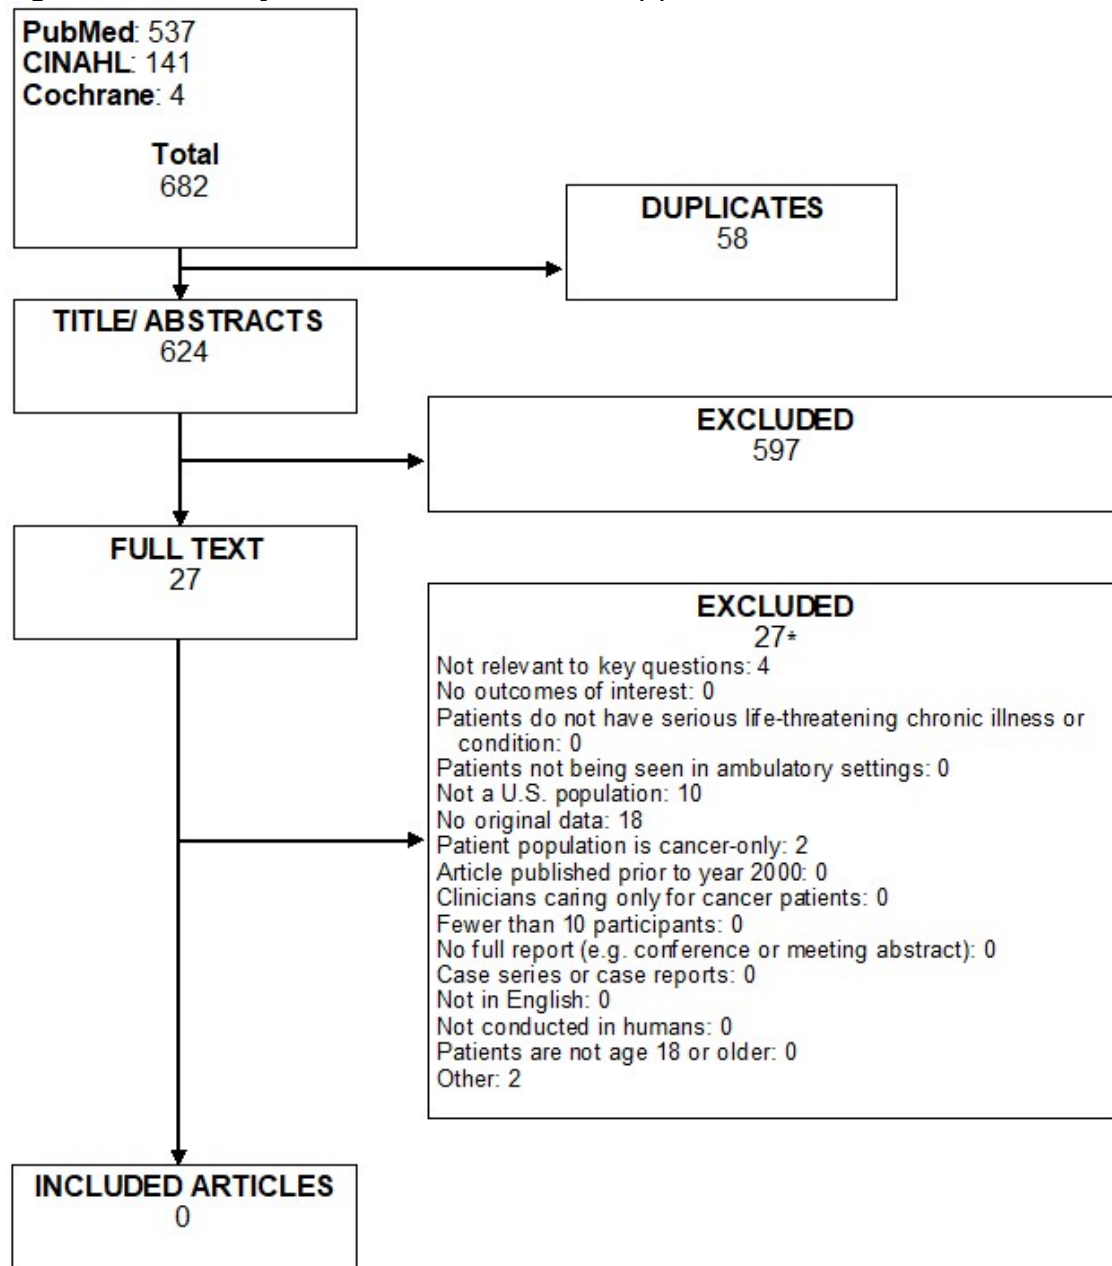

EPEC=Education in Palliative & End-of-life Care

* Sum of excluded articles exceeds 345 because reviewers were not required to agree on reasons for exclusion.

Search Results Part (c) Reviews

We retrieved 624 unique citations (Figure C-3). After screening abstracts and full-text, we included zero studies. Appendix B lists the excluded articles .

Figure C-3. Summary of the literature search Part (c) reviews

U.S.=United States

* Sum of excluded articles exceeds 27 because reviewers were not required to agree on reasons for exclusion.

Characteristics of Included Studies

These tables include study characteristics, inclusion and exclusion criteria, participant characteristics, intervention details, and details on outcomes. Additional details of included studies are found in Appendix D, Evidence Tables.

Included Web Pages

KQ1a: What prediction models, tools, triggers and guidelines and position statements are available about how to identify when and which patients with serious life-threatening chronic illness or conditions in ambulatory settings could benefit from palliative care?

Key Informant Key Points

Clinician/Stakeholder Key Informant Calls: December 4, 2019

KQ4c. How have palliative care training and educational materials (with or without other intervention components) **for non-palliative care clinicians** caring for patients with serious life-threatening chronic illness or conditions in ambulatory settings been implemented? What is the evidence for how, when, and for which clinicians they could best be implemented in care?

Table C-6. Clinician/stakeholder response to Key Question 4c

Concept	Summary of Responses
How, when and for which clinicians could they best be implemented?	Palliative care educational materials for clinicians and their effectiveness Questions about modality; who receives training; what trainings do they need; how does it work inside of training and education programs; how do we direct people to those things; which clinicians to focus on

KQ5c. What are components of models and multimodal interventions for integrating palliative care in ambulatory settings? What models and multimodal interventions have been implemented for key subpopulations? What components and characteristics of these models and multimodal interventions contribute to their effective implementation? What is the evidence for how, when, and for which patients they could best be implemented in care?

Table C-7. Clinician/stakeholder response to Key Question 5c

Concept	Summary of Patient/Caregiver Responses
Components of models	Communication should include discussing illness, understanding treatment options and decision making Domains from the National Consensus Project Guidelines for Palliative Care: Addressing symptoms, including pain as a holistic concept (including existential, emotional, social pain); psychosocial intervention addressing coping Understanding treatment options and risks, burdens and benefits Coordination of follow-up care/ community resources Primary care doctors should “quarterback” palliative care and push it out to the specialist teams Palliative care would best be aided by coordinating care to include pain management specialists, as well as social workers who can provide perspective
Implementation of models -how?	Introducing palliative care requires creating time and space to allow this to happen; primary teams need to be prepared and supported Integration into and simplifying workflow is key, making things easier for primary clinicians through coordination with community resources Key steps and mechanisms include identifying and selecting patients, leveraging systems (payment), documentation systems, connecting patients to community resources, quality measurement and quality improvement, delivery system design, coordinating with informatics systems, explicitly stating focus of intervention/ key outcomes Inter-professional perspectives and considering practice setting are key Exploring what matters most to patients, and what needs can we best meet and how with limited time and multiple priorities Consolidated Framework for Implementation Research most applicable
Implementation of models - when and for which patients?	Consider what type of population by both disease and socioeconomic status, as well as other characteristics. Individual steps: patient identification triggers/reminder systems Specific steps may look different based on primary care vs. other ambulatory (specialty) care

Patient/Caregiver Key Informant Calls: June 18, 2019 and November 20, 2019

KQ4c. How have palliative care training and educational materials (with or without other intervention components) **for non-palliative care clinicians** caring for patients with serious life-threatening chronic illness or conditions in ambulatory settings been implemented? What is the evidence for how, when, and for which clinicians they could best be implemented in care?

Table C-8. Patient/caregiver response to Key Question 4c

Concept	Summary of Patient/Caregiver Responses
How, when and for which clinicians could they best be implemented?	<p>Communication:</p> <p>Patients often learn about palliative care on their own (e.g., in support groups, through work as a patient advocate, or through courses taken), if they are even aware that it exists</p> <p>Developing and providing educational tools to patients and their caregivers could help with communication, but in context of physicians communicating with patients</p> <p>Palliative care training would be helpful, especially to help clinicians obtain necessary listening skills</p>

KQ5c. What are components of models and multimodal interventions for integrating palliative care in ambulatory settings? What models and multimodal interventions have been implemented for key subpopulations? What components and characteristics of these models and multimodal interventions contribute to their effective implementation? What is the evidence for how, when, and for which patients they could best be implemented in care?

Table C-9. Patient/caregiver response to Key Question 5c

Concept	Summary of Patient/Caregiver Responses
Components of models	<p>Identifying patients by: Number of specialists they are in contact with and stated issues/conflicts with compliance or need for additional assistance for their care (e.g., medication costs/compliance, multiple physician appointments/follow-ups, etc.)</p> <p>Include caregivers in discussions and provide them with education</p>
Implementation of models -how, when and for which patients?	<p>Critical for clinicians to initiate discussions and clarify what palliative care is, how it is distinct from hospice, why it is important, and its goals (e.g., to increase quality of life and to be patient-centered)</p> <p>Clinicians should present all available options and be clear about the importance of patient/caregiver involvement in the process</p> <p>Communication about palliative care should occur early, be hands-on/face-to-face, and provide information in a patient-friendly, easily understandable manner and format, aided by educational materials (e.g., discussions, educational brochures, handbooks, etc.)</p>

Website Review

We searched 139 U.S. webpages and identified the following Web resources: 9 about prediction models, tools, and triggers and 5 guidelines and position statements about identifying patients; 13 about educational materials and resources for patients and their caregivers; 5 about shared decision-making tools; 12 about training and educational materials for non-palliative care clinicians; and 2 about models and multimodal interventions for integrating palliative care (see Results Appendix for listing of websites searched). We found no evaluation or study about the effectiveness or implementation of models or multimodal interventions for integrating palliative care for any of the Web resources identified.

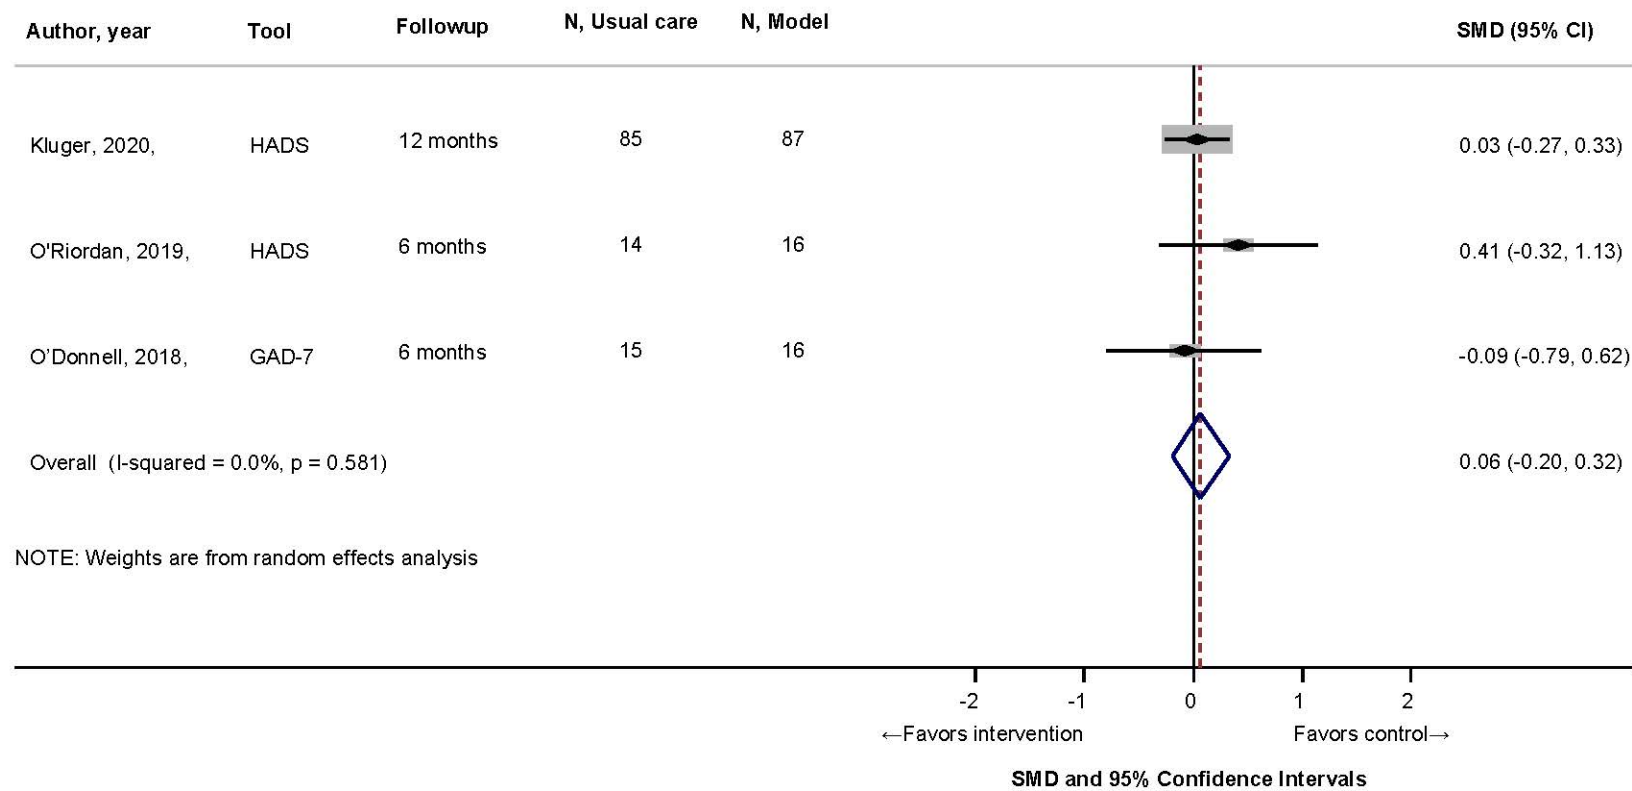

The websites with Web resources included the official sites of two palliative care organizations; three primary care and specialty healthcare professional organizations; three Federal government organizations; four national foundations, with a major focus in palliative care; and four patient organizations. More than half (n=24) of the resource content was focused on advance care planning and included downloadable information and links to other website resources. Patient educational materials and resources focused on palliative care definitions, information, and resources, as well as caregiver information; only one educational resource was available in a language other than English. Healthcare professional training and educational materials were in the form of videos, fact sheets, or modules in a curriculum.

All resources were free, except five resources that were on websites free only to members of the respective organizations. Four of those five exceptions were about prediction models, tools, triggers, and guidelines and position statements available for identification of patients in ambulatory settings who could benefit from palliative care. One of those five exceptions was about palliative care training and educational materials available for non-palliative care clinicians caring for patients with serious life-threatening chronic illness or conditions in ambulatory settings.

Meta-Analysis Figures

Key Question 5b: Meta-analysis of the effectiveness of models and multimodal interventions for integrating palliative care for patients with serious life-threatening chronic illness or conditions in ambulatory settings

Figure C-4. Meta-analysis of the effects of models for integrating palliative care on anxiety in patients with non-cancer serious chronic illness compared with usual care

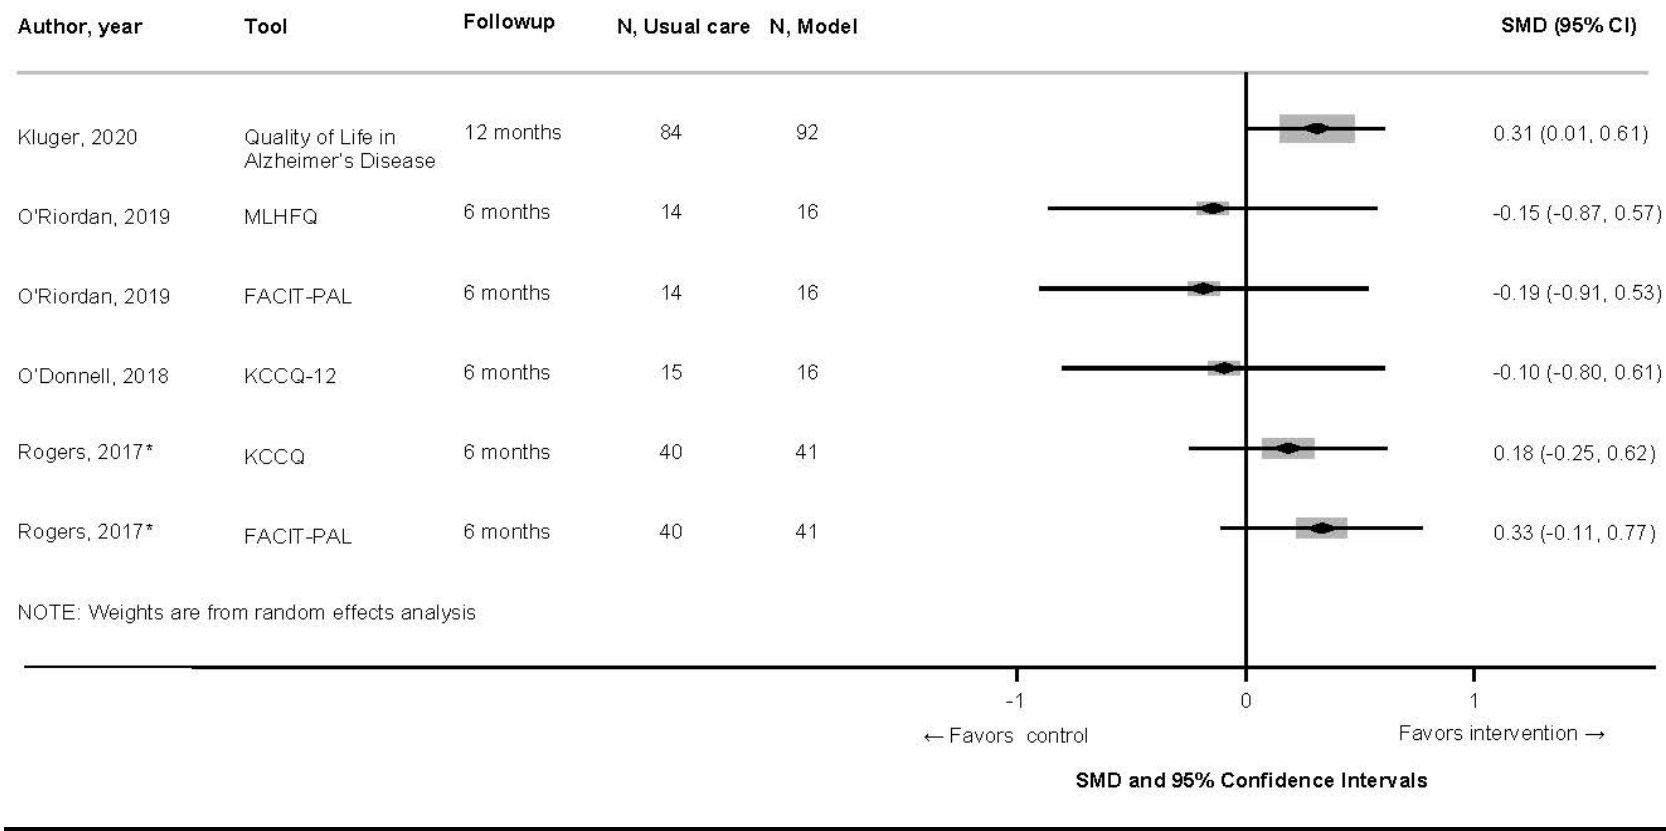

CI=confidence interval; GAD-7=General Anxiety Disorder-seven item; HADS= Hospital Anxiety and Depression Scale; N=sample size; SMD=standardized mean difference

Figure C-5. Meta-analysis of the effects of models for integrating palliative care on psychological well-being in patients with noncancer serious chronic illness compared with usual care

CI=confidence interval; N=sample size; SMD=standardized mean difference

Figure C-6. Forest plot of the effects of models for integrating palliative care on health-related quality of life in patients with non-cancer serious chronic illness compared with usual care

CI=confidence interval; FACIT-PAL=Functional Assessment of Chronic Illness Therapy - Palliative Care; KCCQ=Kansas City Cardiomyopathy Questionnaire; KCCQ-12=Kansas City Cardiomyopathy Questionnaire-12 item; MLHFQ=Minnesota Living with Heart Failure Questionnaire; N=sample size; SMD=standardized mean difference

*Rogers, 2017 et al.¹ standardized mean difference calculated using difference between baseline and outcome at 6 months.

Paladino, 2019 ³³	Arm 2	NA	Training/education: clinician	Train-the-trainer program	Three faculty conducted three train-the-trainer courses to equip faculty trainers at three institutions to teach serious illness communication. The two-day train-the-trainer curricula was based on best educational practices and adult learning theories, including attention to knowledge, attitudes, and skills-oriented practice with feedback. The goal was to prepare faculty trainers to deliver a predesigned, structured 2.5–3-hour clinician training on serious illness communication. The clinician training, tested in two research trials teaches clinicians to have conversations about patients' values, goals, and prognosis using a scalable tool, the Serious Illness Conversation Guide ("Guide"). The training involves interactive methods, including reflection, demonstration and debriefing, cognitive maps, and skills practice with feedback. Rabow, 2003 ³⁴	Arm 2	Comprehensive Care Team (CCT)	Palliative care models	Collaborative care	Included 7 main components. First, consultation with PCPs was based on patient assessments conducted by the social worker. The CCT developed recommendations offered to the patient's PCP via written letter and e-mail. Recommendations were offered in 5 domains: physical symptoms, psychological well-being, social support, spiritual well-being, and advance care planning. The CCT physicians based their suggestions on information from validated patient surveys and the social worker assessment. Second, the social worker provided case management and offered psychological support in person and by telephone. The social worker encouraged patients to address issues of advance care planning, including surrogate decision makers, prognosis, funeral arrangements, and wills. Third, a nurse provided family caregiver training and support through formal classes and informal individual consultation. Fourth, a pharmacist performed a medical chart review of patient medications, looking in particular for drug-drug interactions and unnecessarily complex medication regimens. Fifth, a chaplain offered each patient spiritual and psychological support. Sixth, patients and their families were invited to monthly support groups that included discussions about symptom management and advance care planning, as well as art projects called "art experientials" designed to explore emotions relating to illness and relationships. Seventh, medical and pharmacy students provided volunteer patient support and advocacy through weekly telephone contacts with patients, monthly visits, and regular communication with the CCT about patient needs	In person	Multiple	1 year NA	Multiple Palliative care

Table D-40. Summary of study characteristics for qualitative review

Key Question	Author, Year	Study Qualitative/Implementation Objective(s)	Qualitative Data Collection Method (interviews, focus groups, ethnographies, other)	Qualitative Data Analysis Method (constant comparative, thematic, narrative, other)
3c	Dillon, 2017 ²⁶	To understand how providers incorporate electronic health record ACP documentation into clinical practice	Interviews	Thematic analysis
3c	Metzger, 2016 ³¹	To describe LVAD patients' and surrogates' experiences with, and perspectives on SPIRIT-HF, an advance care planning (ACP) intervention	Interviews	They state (p. 307): "qualitative content analysis techniques" -- though generally seems like: Thematic analysis – secondary analysis of interviews
3c	O'Hare, 2016 ³⁹	To gain insight from providers from a range of disciplines and specialties who care for patients with advanced kidney disease to identify potential opportunities to enhance ACP for this population.	Interviews	Authors describe as "grounded theory", but seems more appropriately described as thematic analysis
3c	Song, 2017 ³⁶	To explore the perspectives of the bereaved surrogates of dialysis patients on the process and impact of an advance care planning intervention and to compare the perceived impacts of the intervention between African Americans and Whites	Interviews	Thematic analysis
3c	Uhler, 2015 ³⁷	To assess the usability of the InformedTogether decision aid	Other: Qualitative Observations	Thematic analysis
4c	Paladino, 2019 ³³	To evaluate whether a novel train-the-trainer model results in high-quality training that improves clinicians' self-reported competencies in serious illness communication	Other: Text analysis	Thematic content analysis
5c	Bekelman, 2011 ⁴⁰	To learn about patients' and their family caregivers' major concerns and needs and to explore whether and how palliative care would be useful to them.	Interviews	Constant Comparison derived from grounded theory
5c	Bekelman, 2014 ²⁴	To determine the feasibility and acceptability of CASA (Collaborative Care to Alleviate Symptoms and Adjust to Illness) and identify necessary improvements	Interviews	Thematic analysis
5c	Bekelman, 2016 ²⁵	To understand organizational factors that could influence the adoption and scale-up of outpatient palliative care in chronic advanced illness, using the example of heart failure	Interviews	Thematic analysis
5c	Goff, 2019 ²⁷	To identify barriers and facilitators for implementation of "Shared Decision Making and Renal Supportive Care" (SDM-RSC), an intervention to improve advance care planning (ACP) for patients with ESKD on hemodialysis	Other: Observations and open-ended survey questions	Thematic analysis
5c	Hobler, 2018 ²⁸	To identify palliative care and advance care planning needs of patients with CF and their families and to identify clinicians' potential roles in meeting these needs.	Interviews	Modified grounded theory approach
5c	Lakin, 2019 ²⁹	To explore the perceptions of primary care clinicians about interprofessional work in serious illness communication	Interviews	Thematic analysis
5c	Long, 2014 ³⁰	To evaluate the feasibility and usefulness of an advance practice nurse delivered palliative care intervention in patients with symptomatic COPD	Interviews	Directed content analysis
5c	Nowels, 2016 ³²	To explore primary care providers' willingness and perceived capacity to provide basic palliative care, and their concerns and perceived barriers	Interviews	Thematic analysis

Key Question	Author, Year	Study Qualitative/Implementation Objective(s)	Qualitative Data Collection Method (interviews, focus groups, ethnographies, other)	Qualitative Data Analysis Method (constant comparative, thematic, narrative, other)
5c	Rabow, 2003 ³⁴	To explore perceptions of the acceptability and benefits of the CCT intervention	Interviews	Thematic analysis
5c	Scherer, 2018 ³⁵	Development of outpatient integrated nephrology and palliative care program	Interviews	Thematic analysis

ACP=advanced care panning; CASA=Collaborative Care to Alleviate Symptoms and Adjust to Illness; CCT=interdisciplinary consultation team; CF=cystic fibrosis; COPD= Chronic obstructive pulmonary disease; ESKD=end stage kidney disease; LVAD=Left Ventricular Assist Device; SDM-RSC=Shared Decision Making and Renal Supportive Care; SPIRIT-HF=Sharing the Patient’s Illness Representations to Increase Trust in Heart Failure.

Table D-41. Results for qualitative review

Author, Year	Themes/Subthemes Identified Relevant to the KQ	Conclusions	Linked to Effectiveness Data
Dillon, 2017 ²⁶	<p>1. Advance directives are vague, and providers find POLST forms more useful for seriously ill patients owing to the level of specificity and detail.</p> <p>2. The provider who sees the patient the most frequently and has a relationship with them should be responsible for advance care planning.</p> <p>3. Lack of interoperability between inpatient and outpatient EHR platforms was a major barrier to documenting ACP; some providers felt time and lack of education about ACP were barriers to doing ACP.</p> <p>4. Facilitators to ACP documentation were having trusting patient-physician relationships, standardized workflows, education for providers, policy changes facilitating a registry, and a “quarterback” take ownership.</p>	Need for: improved interoperability between hospital and outpatient EHR systems, ownership and consensus of which provider should document ACP, and standardized clinic workflows for ACP documentation.	No
Nowels, 2016 ³²	<p>1. Providers felt palliative care should be provided to terminally ill patients or patients in preterminal stages to provide patient and family support.</p> <p>2. Providers typically addressed physical and emotional symptoms of patients but did not often perform a spiritual assessment or engage in goals of care conversations owing to patient/family resistance in acknowledging declining health status. Providers agreed they should manage all or most palliative needs, but several practices delegated to other team members such as SW</p> <p>3. Providers did not feel they were delivering palliative care, but rather supportive care</p> <p>4. Providers described very little community palliative care availability but could refer to hospice</p> <p>5. Providers felt a patient registry, a multidimensional needs assessment, decision aids, and support for care management would help facilitate PC; coaches were helpful for some providers</p> <p>6. PC needs to be financially supported and prioritized by practices</p>	Systematic attention along the multidimensional domains of basic palliative care may enable practices to address the unmet needs of patients with complex illnesses by using existing practice improvement models, strategies, and prioritization.	No
Scherer, 2018 ³⁵	<p>1. Stakeholder needs; subthemes: clinical, operational, and institutional/community</p> <p>2. Challenges to meet stakeholder needs; subthemes: misconception of palliative care, need for clarification of collaborative care, and apprehension concerning practice change</p>	Creation of shared ownership can facilitate innovation and practice change	No

Author, Year	Themes/Subthemes Identified Relevant to the KQ	Conclusions	Linked to Effectiveness Data
Uhler, 2015 ³⁷	<p>1. Although patients and doctors found InformedTogether acceptable and would recommend that doctors use the decision aid with COPD patients, many patients had difficulty understanding the icon arrays that were used to communicate estimated prognoses and could not articulate the definitions of the two treatment choices—Full Code and Do Not Resuscitate (DNR).</p> <p>2. Minor usability problems regarding content, links, layout, and consistency were also identified and corresponding recommendations were outlined. In particular, participants suggested including more information about potential changes in quality of life resulting from the alternative advance directives.</p> <p>3. Some doctor participants thought the decision aid was too long and some thought it may cause nervousness among patients owing to the topic area.</p>	InformedTogether decision aid found acceptable to most COPD patients and doctors. Many patients did not demonstrate understanding of treatment options or prognostic estimates. Patients desired more information on changes in quality of life from the alternative ADs.	No
Paladino, 2019 ³³	<p>1. Scripting was helpful for speed, to allow conversation to flow better, and to take time to appreciate fears and goals</p> <p>2. Helped clinicians learn to initiate the conversation, to “listen more, talk less”</p> <p>3. Clinicians reported that they shouldn’t “let my own worries deter me” as the conversation is very important; paradigm shift from focus on getting a DNR to exploring the questions with patients</p> <p>4. Clinicians felt more comfortable approaching discussion after training</p> <p>“Inquire from patients about their world and illness experience”</p>	Serious illness communication training, delivered through a train-the-trainer model, was highly acceptable and resulted in significant self-reported improvements in competencies of clinicians.	In article -- Yes – Lakin, 2017 ⁸
Bekelman, 2014 ²⁴	<p>1. Majority of patients reported a positive experience with the nursing component as a “good source of information” regarding lifestyle changes and self-monitoring and found it helpful for self-care. Nurse was also an “advocate,” “someone in my corner”</p> <p>2. Majority of patients satisfied with phone call structure of the program owing to flexibility and thought intervention should be provided after diagnosis</p> <p>3. Phone symptom surveys were burdensome and repetitive; grief and loss module not relevant for all patients, as they were not depressed</p>	CASA intervention is feasible and perceived as helpful by participants, based on participant enrollment, cohort retention, implementation of medical recommendations, minimal missing data, and acceptability.	Yes – Bekelman, 2018 ⁸

Author, Year	Themes/Subthemes Identified Relevant to the KQ	Conclusions	Linked to Effectiveness Data
Bekelman, 2016 ²⁵	<p>In order to adopt and scale up outpatient palliative care, there is a need to:</p> <ol style="list-style-type: none"> 1. Develop performance measures for patient-centered care and outcomes that can be used to measure the quality and incentivize the spread of outpatient palliative care 2. Justify additional personnel costs, such as with evidence the costs are offset by other savings or with improvements in patient outcomes and primary care staff workflow. Assess and address practical issues such as staffing and space prior to implementation. 3. Communicate and coordinate with other providers, particularly primary care providers, to maximize buy-in. The nature of communication and coordination (e.g., by phone, through the electronic health record) should be tailored to local and individual preferences. 4. Collaborate with local leaders to determine how outpatient palliative care aligns with local programs (e.g., primary care (PACT), telehealth, mental health, home-based primary care) and needs (e.g., documentation of life-sustaining treatment preferences, referral to and management of patients in hospice) 5. Clarify the roles and responsibilities of outpatient palliative care vs. primary and specialty care for disease management in advanced chronic illnesses such as heart failure. Structure core components of outpatient palliative care to allow for flexibility during implementation 	The combination of policy changes to create incentives and collaboration with local VHA providers and leaders is important in the adoption and scale-up of outpatient palliative care.	No
Lakin, 2019 ²⁹	<ol style="list-style-type: none"> 1. Interprofessional teamwork drives serious illness communication – different views held by members of each of the professions came together to strengthen the output of serious illness conversations; nurses are the champions and leaders of serious illness communication in the case management setting by helping organize tasks, prioritize roles, and remove workflow barriers in a way that enabled serious illness conversations; every clinician has responsibility to take initiative in executing serious illness conversations 2. A conversation is not just a conversation – conversations require multiple levels of preparation, structure helps serious illness communication; personal preparation for the conversation, preparing the environment where the meeting will happen, and preparing the patient/family prior to the conversation; a programmatic approach to conversation ensured they systematically/consistently addressed end-of-life care and goals 3. Relieving some problems reveals other problems – lack of clear roles led to missed opportunities to utilize other professional's expertise; well established relationships within the interdisciplinary team, and with patients improved serious illness communication; explicit care plans following the conversation helped ensure appropriate action (i.e., lack of clarity may result in aggressive treatment that the patient didn't want) 	<p>Three key areas of focus for improving serious illness conversations by interprofessional primary care teams:</p> <ol style="list-style-type: none"> 1- establishing clear professional roles and responsibilities, 2- paying special attention to interprofessional and clinician-patient relationships, and 3- clearly structuring interventions aiming to change the way our system drives serious illness communication. 	Yes – Lakin, 2017 ⁸

Author, Year	Themes/Subthemes Identified Relevant to the KQ	Conclusions	Linked to Effectiveness Data
Hobler, 2018 ²⁸	Three domains of palliative care needs were identified: 1. To be listened to, feel heard, and be “seen” 2. Understanding the context around CF and its trajectory to help with future planning and preparation 3. Information about and potential solutions to circumstances that can cause stress	Patients expressed a need for and openness to palliative care services, as well as some reluctance. They appreciated clinician communication that was open, forthcoming, and attuned to individualized concerns.	No
Long, 2014 ³⁰	1. Improved QoL: The intervention improved QOL by helping with breathing, building self-confidence, recovering more quickly from SOB, and being more active. Feelings of depression resolved after SOB resolved with opioids 2. Issues around study participation: The majority of participants liked the intervention and didn’t suggest changes. Some participants wanted the questionnaires to be more specific to COPD conditions, wanted the intervention to be longer, and addressed “inappropriate” questions about sex and COPD. All liked working with the advanced practice nurse and the majority wanted to continue receiving palliative care. Driving to the clinic was a barrier and recommended coordinating study visits with other clinic visits to ease the burden of travel to clinic. Concerns about taking opioids and cost of paying for pulmonary rehab and PC clinic visits influenced their decision to continue PC after the close of the study 3. Managing expectation: Six participants (46%) talked about how their results from treatment were “nothing drastic” and “slow coming” and “didn’t make enough improvement to continue.” Two said they did not know what to expect early in the study. One said she had been under the impression the study would pay for pulmonary rehabilitation.	Participants reported subjective benefit from palliative care, and the intervention was feasible.	No

Author, Year	Themes/Subthemes Identified Relevant to the KQ	Conclusions	Linked to Effectiveness Data
Rabow, 2003 ³⁴	<p>1. The CCT intervention was acceptable to patients who were still actively seeking disease treatment. The majority of the patients would have wanted the intervention even earlier in the course of their illness and none reported that they would have wanted it later. The interdisciplinary team was well received by patients. They appreciated the intervention's attention to difficult/personal topics such as advanced care planning discussions (even though these discussions were difficult/uncomfortable to the majority) or spirituality,</p> <p>2. Most patients perceived that the CCT intervention improved their sense of connection/satisfaction with caregivers, provided instrumental support, decreased healthcare utilization, improved spiritual well-being, and helped people provide care to other sicker members of their own family,</p> <p>3. All patients reported feeling cared for, valued, listened or receiving compassionate care from CCT. Many reported improved communication and increased sense of connection with their PCP, with family members, and with the medical center</p> <p>4. The CCT intervention led to improved satisfaction in relationships with family members, their PCP, and the medical center as a whole,</p> <p>5. Some patients said involvement in the CCT enabled them to avoid at least one ED visit, hospitalization, PCP, or pharmacy,</p> <p>6. Many participants served as the primary family caregiver for an even more seriously ill relative – they reported their CCT palliative care education helped them care for their loved ones .</p>	<p>Development of a dedicated, interdisciplinary team of providers and volunteers may be beyond the capabilities of some health care institutions. However, some simple and relatively inexpensive components of such an intervention appear to be effective and may be offered by non-medical personnel. These include obtaining social services that patients already qualify for under existing funding mechanisms, facilitating better communication about difficult issues, and offering patients the simple gift of listening with compassion. Patients at the beginning of the end of life want these interventions even earlier in the course of their illness than we might expect. Introducing patients to palliative care philosophy, services, and techniques in the outpatient setting, prior to the drama of hospitalized dying, may provide an opportunity for growth, as well as clarification of the seeming paradox between simultaneously wishing to forestall and needing to prepare for death.</p>	Yes - Rabow, 2004 ²¹
Metzger, 2016 ³¹	<p>1. Sharing the story of their HF (or caregiver telling story) was a positive and essential part of the experience – helped lay the foundation for the rest of the conversation related to end-of-life care; helped reinforce the surrogate decision maker's experience and perspective,</p> <p>2. The intervention brought patients and surrogates increased peace of mind – allowed them to express or clarify their wishes, be more prepared for the “what-ifs,”and have a clearer idea of what outcomes of medical treatments would be unacceptable to the patient. Surrogates felt armed with increased knowledge that increased their preparedness for end of life,</p> <p>3. Advance care planning discussions should take an individualized approach and best timing may vary by person – most surrogates recommended having the conversation before the procedure while some patients suggested waiting until after LVAD placement.</p>	<p>Elements of the intervention, such as including both patients and surrogates, inviting both groups to share their HF stories, focusing on outcomes of treatment options, and beginning or continuing the discussions during a time of relative medical stability, were characterized as particularly important to participants. Because many of the aspects of the intervention listed above are not resource intensive, discipline- or illness-specific, or particularly time-consuming, they could readily be incorporated into patient care, by the clinicians who know the patient best.</p>	Yes – but not included in our references ³⁴

Author, Year	Themes/Subthemes Identified Relevant to the KQ	Conclusions	Linked to Effectiveness Data
Goff, 2019 ²⁷	<ol style="list-style-type: none"> 1. A few patients and family members experienced emotional distress in response to the intervention, but others wanted more specific discussions about their prognosis 2. Social workers felt that the intervention promoted interdisciplinary teamwork and put patients in control of the discussions. Nephrologists were satisfied with the intervention but had concerns about feasibility owing to lack of time with patients 3. Outer setting: dialysis disqualifies patients from receiving hospice services unless they have another life-limiting illness in addition to EKSD 4. Inner setting: lack of clinician time was a potential barrier to the intervention; difficulty scheduling advanced care planning sessions because of clinician's busy schedules; felt it was challenging to estimate allotted time due to patient's emotional responses 5. Personal characteristics of clinicians were potential barriers or facilitators to effective implementation of the intervention – several SW became champions for the interventions while others refused to participate 6. Having info about an individual patient's goals and preferences before the intervention was helpful and a reminder sheet of key components to include in the intervention sessions helped with fidelity – SW recommended having hospice materials available during sessions 7. SW felt the intervention would be improved if dialysis workers received ACP training and if training were interprofessional rather than conducted separately 8. Involvement of national dialysis chain leaders as advisors on the study facilitated implementation because of “buy-in.” 	<p>This study suggests that future efforts to scale-up and implement the SDM-RSC intervention could benefit from additional ACP training for both social workers and nephrologists, including interprofessional training. This study also suggests that some of the barriers identified may be obviated by involving local clinicians, staff, dialysis patients, and their families in decisions about processes for conducting ACP discussions at an early stage of implementation of the intervention. The impact of healthcare policies, such as those that may contribute to a perceived lack of time for ACP discussions in current work flows and challenges to accessing hospice services while on hemodialysis should also be considered if ACP is to become a routine practice for healthcare providers and their patients facing the high morbidity and mortality associated with hemodialysis.</p>	Yes – NCT02405312 ³⁵

Author, Year	Themes/Subthemes Identified Relevant to the KQ	Conclusions	Linked to Effectiveness Data
Song, 2017 ³⁶	<p>PROCESS of SPIRIT themes:</p> <ol style="list-style-type: none">1. The SPIRIT intervention was an opportunity for discussion of topics that had previously been avoided (death, life-sustaining treatments, acceptable/unacceptable outcomes, end-of-life preferences). For some, the appreciation for this opportunity changed over time (i.e., they were uncomfortable at first but then they found it helpful),2. SPIRIT made it easier for patients and surrogates to share their feelings because it started by talking about their experience with the patient's illness rather than starting by talking about death – participants were surprised how comfortable they were talking about it. <p>Impact of SPIRIT themes:</p> <ol style="list-style-type: none">1. SPIRIT was eye-opening – many reported that they didn't realize the life-limiting nature of the patient's illness or that death might be near; many didn't view dialysis as a life-sustaining treatment. Before SPIRIT, people viewed life-sustaining treatment as good or bad, in general, rather than considering circumstances in which life-sustaining treatments may/may not be beneficial. Participants shared understanding of the surrogate's role to make decisions based on patient's (rather than their own) wishes2. SPIRIT made relationships closer by opening up lines of communication and bringing other family members on board,3. SPIRIT helped surrogates feel prepared during the time leading up to end-of-life decision-making by helping them realize the possibility of the patient's death and motivating them to seek info they needed from the patient and others,4. SPIRIT made it easier for surrogates to make decisions and gave them peace of mind with their decisions afterward – a better understanding of their loved one's wishes about end of life was one of the most frequently reported positive outcomes of SPIRIT.	Our data may help explain the beneficial effects of SPIRIT on surrogates, but future trials should include data on control surrogates' perspectives	Yes – Song, 2009 ⁶

Author, Year	Themes/Subthemes Identified Relevant to the KQ	Conclusions	Linked to Effectiveness Data	Additional Comments
O'Hare, 2016 ³⁹	<p>Four themes emerged regarding barriers to ACP for patients with advanced kidney disease:</p> <p>1. Medical Care for Patients with Advanced Kidney Disease Is Complex and Fragmented across Settings and Providers and over Time: Providers may be transient and their reach is often limited to a particular phase of the illness trajectory. Lack of clear understanding of how dialysis decisions are made and by which providers. Providers involved in the later stage of the illness wonder why patients are not better prepared for advanced stages of the disease and were struck by how often patients were blindsided when faced with decisions about dialysis. Most ACP decisions occurred in acute setting rather than clinic setting,</p> <p>2. Lack of a Shared Understanding and Vision of ACP and Its Relationship with Other Aspects of Care: Some providers saw ACP as a series of tasks (ie completing an advanced directive) while as others saw it as an ongoing process that is best supported within an established patient-provider relationship,</p> <p>3. Unclear Locus of Responsibility and Authority for ACP: Not all providers felt responsible for conducting ACP conversations and felt it was someone else's job or that it wasn't within their scope of practice; vague who is in the "driver's seat" of these conversations,</p> <p>4. Lack of Active Collaboration and Communication around ACP: Little open communication around ACP; nurses often felt they had a better grasp of patients' circumstances and priorities than nephrologists and expressed nephrologists not always open with patients about what to expect with dialysis and illness trajectory; mismatch between assigned roles and skills to promote ACP.</p>	<p>Complexity and fragmentation of medical care across settings and providers and over time for patients with advanced kidney disease pose a significant challenge to orchestrating the process of ACP among members of this population. Systematic efforts to promote interdisciplinary collaboration among the diverse providers who care for patients with advanced kidney disease will likely be needed to promote effective ACP in this population.</p>	No	

Author, Year	Themes/Subthemes Identified rRelevant to the KQ	Conclusions	Linked to Effectiveness Data	Additional Comments
Bekelman et al. (2011), 6717	<p>Several key themes emerged regarding the content, structure, and timing of palliative care according to patients and caregivers:</p> <p>Content</p> <p>Help us adjust to the limitations of illness and future course of illness</p> <p>adjusting to the limitations and course of HF was the most difficult part of living with it – ask patients how they are doing with HF in the context of their life</p> <p>Asked for help adjusting to and planning for the uncertain course of illness – wanted more detail about the expected course of illness, although this description varied</p> <p>Reduce symptoms, but can you really do anything to help?</p> <p>Fatigue and shortness of breath as most common and distressing symptoms, but were pessimistic of what could be done to alleviate this</p> <p>Structure</p> <p>Who: The provider should be “familiar with my heart condition”</p> <p>Provider should know patient and caregiver and be familiar with their heart condition; some recommended a mental health provider be part of the team</p> <p>What: Involve caregivers and facilitate communication and coordination</p> <p>Caregivers especially asked providers to involve the family and facilitate better communication and coordination</p> <p>How: Use a “team approach”</p> <p>Timing</p> <p>Need for help adjusting to illness at or shortly after the diagnosis of HF and then over time when needed</p> <p>It’s not for everyone – four patients were not interested in the proposed care time as they felt there was nothing else that could be done to help them, they were stable and wanted to keep things the same, or they were afraid a “care team” would compromise another layer of providers without coordination with existing providers; also concerned about additional appointments.</p>	<p>Findings provide guidance for provision of palliative care to HF patients. Early in HF and then as- needed, programs should involve family caregivers, focus on helping patients and families adjust to the limitations and future of illness, and provide symptom relief complementing disease-specific strategies.</p> <p>Training a nurse or social worker to incorporate these services using a collaborative care, team approach is one care model that our study supports. Future research should test the feasibility and effectiveness of integrating such a program into routine HF care.</p>	No	

ACP=advanced care planning; AD=advanced directive; CASA=Collaborative Care to Alleviate Symptoms and Adjust to Illness; CCT=interdisciplinary consultation team; CF=cystic fibrosis; COPD=Chronic obstructive pulmonary disease; EHR=electronic health records; ESKD=end stage kidney disease; HF=heart failure; PACT=Patient Aligned Care Team; PC=palliative care; PCP=primary care provider; POLST=Provider Orders for Life-Sustaining Treatment; QOL=quality of life; SDM-RSC=Shared Decision Making and Renal Supportive Care; SNR=do not resuscitate; SOB=shortness of breath; SPIRIT=Sharing the Patient’s Illness Representations to Increase Trust; SW=social worker.

Table D-42. Risk of bias assessment of randomized controlled trials

Author, Year	Outcome Assessed	Domain 1: Randomization Process	Domain 2: Deviations Intended Interventions (effect of assignment to intervention)	Domain 2: Deviations Intended Interventions (effect of adhering to intervention)	Domain 3: Missing Outcome Data	Domain 4: Measurement of the Outcome	Domain 5: Selection of the Reported Result	Final Assessment

Table D-47. Percentage of studies meeting criteria using the Joanna Briggs Institute quality assessment

JBI Criteria	% Studies Meeting Criteria
Q1. Is there congruity between the stated philosophical perspective and the research methodology?	25% (4/16)
Q2. Is there congruity between the research methodology and the research question or objectives?	93.8% (15/16)
Q3. Is there congruity between the research methodology and the methods used to collect data?	75% (12/16)
Q4. Is there congruity between the research methodology and the representation and analysis of data?	62.5% (10/16)
Q5. Is their congruity between the research methodology and the interpretation of results?	62.5% (10/16)
Q6. Is there a statement locating the researcher culturally or theoretically?	18.8% (3/16)
Q7. Is the influence of the researcher on the research, and vice-versa, addressed?	12.5% (2/16)
Q8. Are the participants, and their voices, represented?	100% (16/16)
Q9. Is the research ethical according to current criteria or, for recent studies, and is there evidence of ethical approval by an appropriate body?	87.5% (14/16)
Q10. Do the conclusions drawn from the research report flow from the analysis/ interpretation of the data?	68.8% (11/16)

JBI=Joanna Briggs Institute; Q=question.
